Chapter 1: Catalog of Geant sections

Origin   :   **Submitted:** 01.10.84
Revision   :   **Revised:** 20.04.94
Documentation :

Foreword

As the scale and complexity of High Energy Physics experiments increase, simulation studies require more and more care and become essential to

- design and optimise the detectors,

- develop and test the reconstruction and analysis programs, and

- interpret the experimental data.

`GEANT` is a system of detector description and simulation tools that help physicists in such studies. The `GEANT` system can be obtained from `CERN` as six Patchy [8]/CMZ [9] files: `GEANT`, `GEANG`, `GEANH`, `GEANF`, `GEANE` and `GEANX`. The program runs everywhere the CERN Program Library has been installed [1].

The `GEANT` and `GEANG` files contain most of the basic code. The `GEANH` file contains the code for the hadronic showers simulation from the program `GHEISHA` [1]. The `GEANF` file contains the source of the routines for hadronic showers development from the `FLUKA` [2, 3, 4, 5, 6, 101, 102] program which is interfaced with `GEANT` as an alternative to `GHEISHA` to simulate hadronic cascades. The `GEANE` [11] file contains a tracking package to be used, in the context of event reconstruction, for trajectory estimation and error propagation. The `GEANX` file contains the main program for the interactive version of `GEANT` (GXINT) and a few examples of application programs which may help users to get started with `GEANT`.

General information concerning `GEANT`, for example access to the source code, the list of problems and their proposed corrections, the context of utilisation on the CERN machines, the status of some application programs, the acquisition of documentation, etc., are kept up to date through CERN news and InterNet news group (`cern.lgeant`) and an electronic mailing list which is installed on the CERN IBM mainframe (BITnet/EARN node CERNVM). The name of the list is LGEANT (see below how to subscribe).

The first version of `GEANT` was written in 1974 as a bare framework which initially emphasised tracking of a few particles per event through relatively simple detectors. The system has been developed with some continuity over the years [12]

New versions may differ from the previous ones. Some of the modifications may lead to backward incompatibilities. The user is therefore invited to read carefully the Patch `HISTORY` of the current `GEANT` file where all changes are described in detail.

The development and the maintenance of `GEANT` are possible only thanks to the devoted and continuous collaboration of physicists around the world who use the program and contribute their feedback to the authors and maintainers at CERN. It is of course impossible to mention all of them, and new names are added frequently to the list of the contributors. The `GEANT` team wish to thank them all and expresses its hope that they will continue to help us.

`GEANT` version 3 originated from an idea of René Brun and Andy McPherson in 1982 during the development of the OPAL simulation program. GEANT3 was based on the skeleton of `GEANT` version 2 code [12].

In close collaboration with René and Andy, Pietro Zanarini developed the first versions of the graphics system as well as the early versions of the interactive package initially based on `ZCEDEX`, then upgraded to `KUIP`.

---

[1]At the moment of writing these are the systems on which the CERN Program Library is maintained: VM/CMS-HPO-XA-ESA, SUN, Silicon Graphics, CRAY Y-XMP, Apollo 3000 series, Apollo 10000, HP 400 series, HP 700 series, IBM RS/6000, IBM AIX/370, VAX/VMS, Alliant, Dec Ultrix, NeXT, IBM MVS-HPO-XA-ESA, Convex, MAC/MPW (partial implementation), PC-DOS, PC-Linux, PC-Windows/NT.

Glenn Patrick (RAL) implemented a first version of the electromagnetic processes. Tony Baroncelli (Roma) helped in interfacing `GEANT` to his hadronic shower package `TATINA`. Federico Carminati contributed to the interface with `GHEISHA`, an hadronic shower package developed by Harn Fesefeldt (Aachen).

Francis Bruyant and Michel Maire (LAPP) made substantial contributions to the geometry, tracking and physics parts of `GEANT` while adapting the system to the L3 environment. Francis has been, for many years, an essential collaborator, testing new ideas for the geometry and hits packages. Michel, together with Elemer Nagy and Vincenzo Innocente, developed the `GEANE` system.

A very important contribution to `GEANT` has been made by László Urbán (KFKI Budapest) who has continuously improved the electromagnetic physics package. Lazlo has spent a considerable amount of time in reading the relevant papers in the literature and in making comparisons with experimental results.

René Brun has coordinated the development and the maintenance of `GEANT` from 1982 until 1991 (versions 3.00 up to 3.14). Federico Carminati coordinated the development of the versions 3.15 and 3.16 between 1991 and 1993. Since January 1994, the responsability for `GEANT` is in the hands of Simone Giani. Before assuming this responsability, Simone made substantial improvements in the graphics and interactive packages. After he has enhanced the power of the geometry package and the performance of the tracking for a new version of `GEANT`: in March 1994 the version 3.21 has been released and is the current version of `GEANT`.

Many people contributed their work or their experience. We have tried to acknowledge their names in the manual pages and we apologise for any omissions.

Special mention should be made here of the following contributions:

S.Banerjee (contribution to the tracking package), R.Jones (contribution to the simulation of electromagnetic processes), K.Lassila-Perini (interface with FLUKA and MICAP), G.Lynch (contribution to the multiple scattering algorithms), E.Tchernyaev (original code for hidden-line removal graphics), J.Salt (original interface to the GC package).

S. Ravndal did a complete revision and update of the full documentation for the release of `GEANT` version 3.21.

Special thanks should go to the authors of the packages interfaced with `GEANT`, and in particular to Harn Fesefeldt (`GHEISHA`) and Alfredo Ferrari (`FLUKA` see later). Their patience in explaining the internals of their code, their experience and their collaborative and open attitude have been instrumental.

Another special thanks goes to Mike Metcalf, who helped to improve the English and the structure of the manual.

Any reader who is not familiar with `GEANT` should first have a glance at the notes numbered 001 to 009 in each section of this manual.

Despite our efforts, the documentation is still incomplete and far from perfect. We accept full responsibility for its present status.

Finally, we express our thanks to Michel Goossens for translating the SCRIPT/SGML source of the original `GEANT` manual into LaTeX.

1   The GEANT-FLUKA interface

Since version 3.15, `GEANT` includes an interface with some `FLUKA` [2, 3, 4, 5, 6, 101, 102] routines. This part has been updated and extended in subsequent releases.

`FLUKA` is a standalone code with its own life. Only a few parts have been included into `GEANT`, namely the ones dealing with hadronic elastic and inelastic interactions.

The implementation of `FLUKA` routines in `GEANT` does not include any change, apart from interface ones and those agreed by the `FLUKA` authors. Whenever different options are available in `FLUKA`, the one suggested by the authors have been retained. Nevertheless the results obtained with `FLUKA` routines inside `GEANT` could not be representative of the full `FLUKA` performances, since they generally depend on other parts which are `GEANT` specific.

The routines made available for `GEANT` have been extensively tested and are reasonably robust. They usually do not represent the latest `FLUKA` developments, since the policy is to supply for `GEANT` well tested and reliable code rather than very recent developments with possibly better physics but also still undetected errors.

It is important that `GEANT` users are aware of the conditions at which this code has been kindly made available:

- relevant authorship and references about `FLUKA` [2, 3, 4, 5, 6, 101, 102] should be clearly indicated in any publication reporting results obtained with this code;

- the `FLUKA` authors reserve the right of publishing about the physical models they developed and implemented inside `FLUKA`, `GEANT` users are not supposed to extract from the `GEANT-FLUKA` code the relevant routines running them standalone for benchmarks;

- more generally, `FLUKA` routines contained in the `GEANF` file are supposed to be included and used with `GEANT` only: any other use must be authorised by the `FLUKA` authors.

2   Documentation

The main source of documentation on `GEANT` is this manual. Users are invited to notify any correction or suggestion to the authors.

A detailed description of the history of modifications to the `GEANT` code is contained in the `$VERSION` Patch in the `GEANT` file.

`GEANT` is part of the CERN Program Library, and problems or questions about `GEANT` should be directed to the Program Library Office (see next section).

`GEANT` problems can be submitted to an InterNet discussion group `cern.lgeant`.

A mailing list is maintained on CERN's central IBM machine (BITnet node CERNVM) via the LISTSERV mechanism. LISTSERV acts as a rudimentary conferencing system, which forwards the mail received to all subscribed users and to the InterNet group `cern.lgeant`. The list is accessible to all users who have an e-mail connection to CERNVM. To subscribe to the list from a BITnet node a user has to send the following message to LISTSERV at CERNVM using the local BITnet message facility:

<div align="center">

SUBSCRIBE LGEANT

</div>

From a non-BITnet node, the user can send an ordinary mail message to the user LISTSERV at CERNVM containing that single line.

Together with the `GEANT` library comes a *correction cradle* (see section on maintenance policy) which contains the history of the modifications to the current version of the `GEANT` program. This file is accessible to all users in the PRO area and can be found in:

<div align="center">

GCORR*xxx*.CAR

</div>

where *xxx* is the version number.

Documentation on the elements of the CERN Program Library used by the `GEANT` program is available from the CERN Program Library Office.

3   Update policy

The `GEANT` program is constantly updated to reflect corrections, most of the time originating from users' feed-back, and improvements to the code. This constant evolution, which is one of the reasons for the success of `GEANT`, poses the serious problem of managing change without disrupting stability, which is very important for physicists doing long production runs.

In the CERN Program Library maintenance scheme, three versions of any product are present at the same time on the central systems, in the OLD, PRO and NEW areas with those same names. This scheme does not

apply to `GEANT` because every new release usually contains modifications in the physics which can produce, we hope, better but often different results with respect to the previous version. It is therefore appropriate to offer to the users an extra level of protection against running inadvertedly the wrong version by appending the version number to all the files of `GEANT`. In this way the users will have to change their procedure to change the version of `GEANT`.

On the other hand, the new user should not bother about version numbers and correction files, and so an alias is installed on all systems without any version number, always pointing to the latest released version.

As said before, users' feed-back is of paramount importance in detecting problems or areas for improvement in the system, so the new version is made available in the NEW area well before the official release. If, on the one hand, those who use this version do so at their own risk, on the other hand users are encouraged to perform as much testing as possible, in order to detect the maximum number of problems before the final release. Modifications in the pre-release version are made directly in the source code.

When problems are discovered, which may seriously affect the validity of the results of the simulation, they are corrected and the library recompiled in the /new area. To minimise network transfer for remote users and in the interest of the stability of the system, the source code of the released version in PRO is not touched, but rather the correction is applied via a so-called *correction cradle* which is a file containing the differences between the original and the corrected version in a format required by PATCHY/CMZ. Both these programs can read the original source and the correction cradle and produce the corrected source. The corrected car/cmz source and the corrected binary library are made then available in /pro at the following CERNLIB release (when /new becomes /pro).

The cmz source files contain the full history of the corrections applied with proper versioning, so that every intermediate version can be rebuild. Users at CERN should not need to use the correction cradle other than for documentation purposes. Remote users may want to obtain the cradle and apply the corrections. At every CERNLIB release the correction cradle is obviously reset to be empty, as all the corrections have been applied in the code directly. The correction cradle for the OLD version is available but has to be considered frozen. No correction is ever applied to an old version.

New versions of `GEANT` are moved into the PRO area synchronously with releases of the CERN Program Library. If no new version of `GEANT` is available at the time of the release of the Program Library, the `GEANT` files do not change their location and the production version remains the same.

4   Availability of the documentation

This document has been produced using LaTeX[2] with the `cernman` and `cerngeant` style options, developed at CERN. A printable version of each of the sections described in this manual can be obtained as a compressed PostScript file from CERN by anonymous ftp. You can look in the directory described in the procedure below for more details. For instance, if you want to transfer the description of the physics routines, then you can type the following (commands that you have to type are underlined):[3]

```
ftp asis01.cern.ch
Trying 128.141.201.136...
Connected to asis01.cern.ch.
220 asis01 FTP server (SunOS 4.1) ready.
Name (asis01:username): anonymous
Password: your_mailaddress
ftp> binary
ftp> cd cernlib/doc/ps.dir/geant
ftp> get phys.ps.Z
ftp> quit
```

---

[2] Leslie Lamport, LaTeX – *A Document Preparation System*. Addison–Wesley, 1985
[3] You can of course issue multiple `get` commands in one run.

Introduction to the manual

The present documentation is divided into sections which follow the structure of `GEANT` and its major functions. Each section is identified by a *keyword* which indicates its content. Sections are in alphabetical order:

`AAAA`	introduction to the system;
`BASE`	`GEANT` framework and user interfaces to be read first;
`CONS`	particles, materials and tracking medium parameters;
`DRAW`	the drawing package, interfaced to `HIGZ`;
`GEOM`	the geometry package;
`HITS`	the detector response package;
`IOPA`	the I/O package;
`KINE`	event generators and kinematic structures;
`PHYS`	physics processes;
`TRAK`	the tracking package;
`XINT`	interactive user interface;
`ZZZZ`	appendix.

Within each section, the principal system functions or the details of subroutines are described in a series of *papers* numbered from 001 to 999. In the upper left corner it is indicated in which `Geant` release the subroutines were introduced and left unchanged. The authors of the conceptual ideas or/and of the early versions of the code are acknowledged under the item **Origin**, while **Revision** contains the contributors to any important upgrade. **Documentation** is essential, but sometime implies a not negligeable amount of work. When relevant these contributions are acknowledged here. In addition all reported bugs, accepted suggestions...etc...are mentioned in the history part of the source code and correction cradle.

Subroutines which are not necessary for an understanding of the program flow and which are not intended to be called directly by the user have been omitted.

The notation `[<KEYW>nnn]` is used whenever additional information can be found in the quoted section. In the description of subroutine calling sequences, the arguments used both on input and on output are preceded by a * and the output arguments are followed by a * .

For convenience, two more sections have been added: the section `AAAA`, for general introductory information at the beginning, and the section `ZZZZ`, for various appendices and indexed lists, at the end.

A table of contents is available in `AAAA000`. To ease access to this documentation an index appears in `ZZZZ999`. It gives in alphabetic order the names of all documented `GEANT` subroutines with references to the appropriate write up(s).

A short write up of `GEANT` can be obtained by collecting the papers numbered 001 to 009 in each section.

Introduction to `GEANT`

1   `GEANT` applications

The `GEANT` program simulates the passage of elementary particles through the matter. Originally designed for the High Energy Physics experiments, it has today found applications also outside this domain in areas such as medical and biological sciences, radio-protection and astronautics.

The principal applications of `GEANT` in High Energy Physics are:

- the *transport* of particles (*tracking* in this manual) through an experimental setup for the simulation of detector response;

- the graphical representation of the setup and of the particle trajectories.

The two functions are combined in the interactive version of `GEANT`. This is very useful, since the direct observation of what happens to a particle inside the detector makes the debugging easier and may reveal possible weakness of the setup (also sometimes of the program!).

In view of these applications, the `GEANT` system allows you to:

- describe an experimental setup by a structure of geometrical volumes. A `MEDIUM` number is assigned to each volume by the user ([`GEOM`]). Different volumes may have the same medium number. A medium is defined by the so-called `TRACKING MEDIUM` parameters, which include reference to the `MATERIAL` filling the volume [`CONS`];

- accept events simulated by Monte Carlo generators [`KINE`];

- transport particles through the various regions of the setup, taking into account geometrical volume boundaries and physical effects according to the nature of the particles themselves, their interactions with matter and the magnetic field [`TRAK`], [`PHYS`];

- record particle trajectories and the response of the sensitive detectors [`TRAK`], [`HITS`];

- visualise the detectors and the particle trajectories [`DRAW`], [`XINT`].

The program contains *dummy* and *default* user subroutines called whenever application-dependent actions are expected.

It is the responsibility of the user to:

- code the relevant user subroutines providing the data describing the experimental environment;

- assemble the appropriate program segments and utilities into an executable program;

- compose the appropriate data records which control the execution of the program.

The section [`BASE`] of this manual gives more information on the above.

Note: the names of the dummy or default user subroutines have `GU` or `UG` as their first two letters.

2 Event simulation framework

The framework offered by `GEANT` for event simulation is described in the following paragraphs, in order to familiarise the reader with the areas where user interventions are expected. For each item we will indicate in brackets the relevant section where more information can be found.

At the same time, the `GEANT` data structures are introduced. This is important as the coding to be provided by the user most often consists of storing and retrieving information from data structures, or reading or writing data structures. For simple applications user routines are provided as an interface to the data structures partially hiding them from the users. For advanced users of `GEANT`, some idea of the layout of the data in memory is helpful. `GEANT` data structures are logically related set of data which are physically stored in the `/GCBANK/` common block. The position of each structure is contained in an `INTEGER` variable which is constantly kept up-to-date by `ZEBRA`. By convention the names of these variable, called *pointers* begin with `J`, and they are used in this manual to designate the structure they point to.

A main program has to be provided by the user (`[BASE100]`) for *batch* type operation. For interactive operation a main program is provided, both binary and source, in the library directory both at CERN and in the standard distribution tape of the CERN Program Library. The file is called `gxint<ver>.<ext>`, where `<ver>` is the version of `GEANT` to which this file belongs and `<ext>` is the system-dependent file-name extension to denote a FORTRAN source or an object file. This file should be loaded in front of all other files when assembling a `GEANT` application. The source is provided in case the user wants to modify it, in particular changing the size of the commons `/GCBANK/` or `/PAWC/`.

The main program allocates the dynamic memory for `ZEBRA` and `HBOOK` and passes control to the three phases of the run:

1. initialisation

2. event processing

3. termination

where in each of the three phases the user can implement his own code in the appropriate routines.

3 Initialisation

The initialisation is controlled by the user in the subroutine `UGINIT` who has the responsibility to call the appropriate routines (`[BASE100]`). It consists of the following steps, most of them performed through calls to `GEANT` subroutines:

`GINIT`	initialise the `GEANT` common blocks with default values (`[ZZZZ010]`, `[BASE110]`);
`GFFGO`	read *free format* data records either to modify the default options (`[BASE040]`, `[BASE110]`) or to provide information on the current run;
`GZINIT`	initialise the memory manager, the link areas and the run header bank `JRUNG` (`[BASE110]`);
`GDINIT`	initialise the drawing package (`[DRAW]`), calling this routine without having initialised the graphics package via a call to `IGINIT` or `HPLINT` will cause `GEANT` to abort;
`GPART`	(or `GSPART`) fill the data structure `JPART` with the particle properties (`[CONS]`);
`GMATE`	(or `GSMATE`) fill the data structure `JMATE` with the characteristics of the materials used (`[CONS]`);
`User code`	it is the responsibility of the user to:

- define the geometry of the different components of the setup (`[GEOM]`), stored in the `JROTM` and `JVOLUM` data structures;

- define tracking medium parameters (`[CONS]`,`[TRAK]`), stored in the `JTMED` data structure;

- specify which elements of the geometrical setup should be considered as *sensitive detectors*, giving a *response* when hit by a particle (`[HITS]`);
- usually all done in a user routine called `UGEOM`;

`GGCLOS`   process all the geometrical information provided by the user and prepare for particle transport;

`GBHSTA`   book standard `GEANT` histograms if required by the user with the data record `HSTA` (`[BASE040]`, `[BASE110]`);

`GPHYSI`   compute energy loss and cross-section tables and store them in the data structure `JMATE` (`[CONS]`, `[PHYS]`).

4 Event processing

The processing phase is triggered by a call to the subroutine `GRUN` which, for each event to be processed, gives control to the subroutines:

`GTRIGI`   initialise event processing and create the event header bank `JHEAD`;

`GTRIG`   process one event;

`GTRIGC`   clean up the portion of memory used by the event and check that enough time is left for the next event (`[BASE200]`).

`GTRIG` calls the following user routines:

`GUKINE`   generates or reads (`[IOPA]`) the kinematics of the event and stores it in the data structures `JVERTX` and `JKINE` (`[KINE]`);

`GUTREV`   calling `GTREVE` which performs the following operations for each vertex in turn:

1. moves all the particles attached to the vertex from the permanent stack `JKINE` to the temporary stack `JSTAK`;

2. controls the propagation of each particle though the setup by calling `GUTRAK/GTRACK` (`[TRAK]`); each particle is tracked in turn and when a sensitive detector is traversed, the user may store any useful information in the data structure `JHITS` via the routines described in the section `[HITS]`;

The `JSTAK` data structure is a LIFO (Last In – First Out) stack. Secondary products generated by the current particle transported are processed before proceeding to the next particle. It is very important to understand that by default `GEANT` does not follow the secondary particles generated. It is the responsibility of the user to indicate which particles should be followed via the routines `GSKING/GSKPHO`.

The data structure `JXYZ`, containing the coordinates of space points along the tracks, can be filled by the user during tracking (`[TRAK]`).

`GUDIGI`   simulate the detector responses for the event, using the information recorded in the data structure `JHITS` during particle transport, and store the results in the data structure `JDIGI` (`[HITS]`);

`GUOUT`   perform all the processing at the end of the event and output the relevant data structures (`[IOPA]`).

Other routines called during the tracking phase triggered by `GTREVE` should be mentioned for completeness:

- hadronic interactions can be simulated via either the `GHEISHA` [1] or `FLUKA` [2, 3, 4, 5, 6] hadronic shower generator. In the subroutines `GUPHAD` and `GUHADR` (`[TRAK]`) the user may select the hadronic shower generation program to be used. The default for `GEANT` is `GHEISHA`;

- after each tracking step along the track, control is given to the subroutine `GUSTEP`. From the information available in labelled common blocks the user is able to take the appropriate action, such as storing a hit or transferring a secondary product either in the stack `JSTAK` or in the event structure `JVERTX/JKINE` via the subroutine `GSKING`. In the subroutine `GSSTAK`, called by `GSKING`, a user routine `GUSKIP` is called which permits skipping any unwanted track before entering it in the stack for subsequent transport;

- the subroutine `GUSWIM` is called by the the routines which transport charged particles when in a magnetic field; it selects and calls the appropriate routine to transport the particle. Although formally a user routine, the default version provided by `GEANT` is usually appropriate for most situations. The magnetic field, unless it is constant along the `Z` axis, has to be described via the subroutine `GUFLD`.

5   Termination

The termination phase is under the control of the user (`[BASE300]`) via the routine `GULAST`. In simple cases it may consist of a call to the subroutine `GLAST` which computes and prints some statistical information (time per event, use of dynamic memory, etc.).

Simplified Program Flow Chart

MAIN	user routine
GZEBRA	initialisation of ZEBRA system, dynamic core allocation
UGINIT	user routine
GINIT	initialisation of `GEANT` variables
GFFGO	interpretation of data records
GZINIT	initialisation of ZEBRA core divisions and link areas
GPART/GSPART	creation of the *particle* data structure `JPART`
GMATE/GSMATE	creation of the *material* data structure `JMATE`
user code	description of the geometrical setup, of the sensitive detectors, creation of data structures `JVOLUM, JTMED, JROTM, JSETS`
GPHYSI	preparation of cross-section and energy-loss tables for all used materials
GRUN	loop over events
GTRIGI	initialisation for event processing
GTRIG	event processing
GUKINE	(user) generation (or input) of event initial kinematics
GUTREV	(user)
GTREVE	loop over tracks, including any secondaries generated
GUTRAK	(user)
GTRACK	control tracking of current track
GFINDS	find current volume in the geometry tree
GUSTEP	(user) recording of hits in data structure `JHITS` and of space points in data structure `JXYZ`
GUPARA	called if the particle falls below the tracking threshold
GTGAMA/GTELEC/...	tracking of particle according to type
GFSTAT	fill banks for volume statistics
GSTRAC	store information of the current track segment
GUSTEP	(user) recording of hits in data structure `JHITS` and of space points in data structure `JXYZ`
GTMEDI	finds in which volume/medium the current space point is
GUSTEP	(user) recording of hits in data structure `JHITS` and of space points in data structure `JXYZ`
GUDIGI	computation of digitisations and recording in data structure `JDIGI`
GUOUT	output of current event
GTRIGC	clearing of memory for next event
UGLAST	(user)
GLAST	standard `GEANT` termination

The data structures and their relationship

1   Dynamic memory

The GEANT data structures are stored in the common /GCBANK/ accessible through the following Patchy sequence: The /GCLINK/ variables are pointers to the GEANT data structures in the /GCBANK/ common. They belong to a permanent area declared in GZINIT.

```
+SEQ /GCBANK/   Dynamic core for the GEANT data structures
```

```
      PARAMETER (KWBANK=69000,KWWORK=5200)

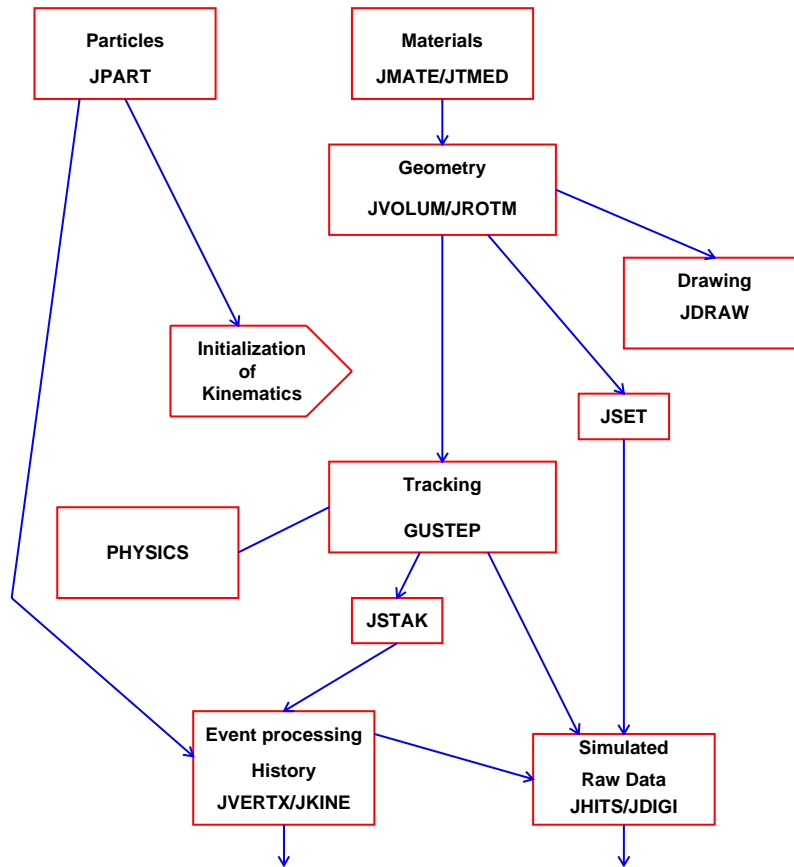

Figure 1: Relation between `GEANT` data structures

2   Common blocks

The communication between program segments of the `GEANT` system is assured by the contents of the data structures and by the definition of *long range* variables in several common blocks. In addition, within the program segments, the subroutines communicate with each other through actual arguments and through the common block variables. A detailed list of the user accessed common blocks is given in `[ZZZZ010]`. Their also the variables initialized in `GINIT` and the possibility in overriding them through data records `[BASE040]` or interactive commands `[XINT]` are specified.

In most of the cases there is a correspondence between a given data structure and a given common block where the current contents of the banks are stored. The labelled common blocks are accessible through Patchy/CMZ sequences identified by the name of the `COMMON`. They are defined in the Patch `GCDES`.

Note:

Unless otherwise specified, the long range variables are initialised in `GINIT`. When non-zero, default values are quoted between brackets. If the value may be modified the keyword for the data record and for the interactive command is also given in bold characters between brackets.

Summary of Data Records

1   Introduction

`GEANT` uses the `FFREAD` [7] package to read *free format* data records in the routine `GFFGO`. The keywords accepted by `GFFGO` can be classified as:

1. general control of the run;
2. control of the physics processes;
3. debug and I/O operations;
4. user applications;
5. Lund event generation.

The data records are listed below by category with the following information:

`KEY`   keyword, any number of characters truncated to the first 4 unless otherwise specified by the user;
`N`   maximum expected number of variables (`NVAR`);
`T`   type of these variables (`I=INTEGER, R=REAL or M=MIXED`) and for each variable in turn:

 • variable FORTRAN name;
 • short description (more detail in [`ZZZZ010`]);
 • labelled common where it is stored;
 • default value, usually from `GINIT`.

When a record is decoded, the values entered by the user in free format are assigned to the variables in order. The number of values can be less than `NVAR`. In case of a `MIXED` type the values entered have agree with the type of the corresponding variable.
For example the data record:

```
    RUNG   5   201
```

presets the run and event number to 5 and 201 respectively. None of the records mentioned below is mandatory.

2   User defined data records

Before calling `GFFGO` the user may define private data records through calls to `FFKEY` as follows:

```
    CALL FFKEY('key',VAR(1),NVAR,'type')
```

They will be interpreted by `GFFGO` in the same way as the `GEANT` pre-defined records.

3   Summary of `GEANT` data records

3.1   General control

KEY	N	I	VAR	Short description	COMMON	GINIT
HSTA	20	M	LHSTA	names of required standard histograms, see [`BASE110`]	/GCLIST/	Blank
OPTI	1	I	IOPTI	automatic optimisation of the geometry via `GSORD`	/GCOPTI/	1
RNDM	2	I	NRNDM	initial random number seed (2 words)	/GCFLAG/	0
RUNG	2	I	IDRUN	user run number	/GCFLAG/	1
			IDEVT	first user event number	/GCFLAG/	1
SORD	1	I	ISTORD	stack ordering flag	/GCSTAK/	0
TRIG	1	I	NEVENT	total number of events to process	/GCFLAG/	10000000
TIME	3	M	TIMINT	time left after initialisation (see **Note below**)	/GCTIME/	
			TIMEND	time required for termination	/GCTIME/	1
			ITIME	test every `ITIME` events	/GCTIME/	1

Note: the time allowed for the job after initialisation cannot be set by the user via the data record. To set the total time for the job the user should call the `TIMEST` routine at the beginning of the program before any call to `GEANT` routines. This variable in the data record has not been removed for backward compatibility.

3.2   Control of physics processes

For more information on the use of these flags, see [`PHYS001`].

KEY	N	I	VAR	Short description	COMMON	GINIT
`ANNI`	1	I	`IANNI`	annihilation	`/GCPHYS/`	1
`AUTO`	1	I	`IGAUTO`	automatic computation of the tracking medium parameters	`/GCTRAK/`	1
`BREM`	1	I	`IBREM`	bremsstrahlung	`/GCPHYS/`	1
`CKOV`	1	I	`ICKOV`	Čerenkov photon generation	`/GCTMED/`	0
`COMP`	1	I	`ICOMP`	Compton scattering	`/GCPHYS/`	1
`CUTS`	16	R		Kinetic energy cuts in GeV:		
			`CUTGAM`	cut for for gammas	`/GCCUTS/`	0.001
			`CUTELE`	cut for electrons	`/GCCUTS/`	0.001
			`CUTNEU`	cut for neutral hadrons	`/GCCUTS/`	0.01
			`CUTHAD`	cut for charged hadrons	`/GCCUTS/`	0.01
			`CUTMUO`	cut for muons	`/GCCUTS/`	0.01
			`BCUTE`	cut for electron bremsstrahlung	`/GCCUTS/`	`GUTGAM`
			`BCUTM`	cut for muon and hadron bremsstrahlung	`/GCCUTS/`	`CUTGAM`
			`DCUTE`	cut for δ-rays by electrons	`/GCCUTS/`	10^4
			`DCUTM`	cut for δ-rays by muons	`/GCCUTS/`	10^4
			`PPCUTM`	total energy cut for direct pair production by muons	`/GCCUTS/`	0.01
			`TOFMAX`	time of flight cut in seconds	`/GCCUTS/`	10^{10}
			`GCUTS`	5 user words	`/GCCUTS/`	0
`DCAY`	1	I	`IDCAY`	decay	`/GCPHYS/`	1
`DRAY`	1	I	`IDRAY`	δ-ray	`/GCPHYS/`	1
KEY	N	I	VAR	Short description	COMMON	GINIT
`ERAN`	3	M		cross-section tables structure:		
		R	`EKMIN`	minimum energy for the cross-section tables	`/GCMULO/`	10^{-5}
		R	`EKMAX`	maximum energy for the cross-section tables	`/GCMULO/`	10^4
		I	`NEKBIN`	number of logarithmic bins for cross-section tables	`/GCMULO/`	90
`HADR`	1	I	`IHADR`	hadronic process	`/GCPHYS/`	1
`LABS`	1	I	`ILABS`	Čerenkov light absorbtion	`/GCPHYS/`	0
`LOSS`	1	I	`ILOSS`	energy loss	`/GCPHYS/`	2
`MULS`	1	I	`IMULS`	multiple scattering	`/GCPHYS/`	1
`MUNU`	1	I	`IMUNU`	muon nuclear interaction	`/GCPHYS/`	1
`PAIR`	1	I	`IPAIR`	pair production	`/GCPHYS/`	1
`PFIS`	1	I	`IPFIS`	photofission	`/GCPHYS/`	0
`PHOT`	1	I	`IPHOT`	photo electric effect	`/GCPHYS/`	1
`RAYL`	1	I	`IRAYL`	Rayleigh scattering	`/GCPHYS/`	0
`STRA`	1	I	`ISTRA`	energy fluctuation model	`/GCPHYS/`	0
`SYNC`	1	I	`ISYNC`	synchrotron radiation generation	`/GCPHYS/`	0

3.3   Debug and I/O operations

KEY	N	I	VAR	Short description	COMMON	GINIT
`DEBU`	3	M	`IDEMIN`	first event to debug.	`/GCFLAG/`	0
			`IDEMAX`	last event to debug	`/GCFLAG/`	0
			`ITEST`	print control frequency	`/GCFLAG/`	0
`GET`	20	M	`LGET`	`NGET` names of data structures to fetch (see **Note**)	`/GCLIST/`	`Blank`
`PRIN`	20	M	`LPRIN`	`NPRIN` user keywords to print data structure (see **Note**)	`/GCLIST/`	`Blank`
`RGET`	20	M	`LRGET`	`NRGET` names of data structures to fetch from RZ files (see **Note**)	`/GCRZ/`	`Blank`
`RSAV`	20	M	`LRSAVE`	`NRSAVE` names of data structures to save from RZ files (see **Note**)	`/GCRZ/`	`Blank`
`SAVE`	20	M	`LSAVE`	`NSAVE` names of data structures to save (see **Note**)	`/GCLIST/`	`Blank`
`SWIT`	10	I	`ISWIT`	user flags for debug	`/GCFLAG/`	0

Note: the user data records for I/O have no effect on the `GEANT` system, and the user is supposed to analyse them at run time and take corresponding action. For instance, a use of the `PRIN` data record could be the following:

```
      CALL GLOOK('VOLU',LPRIN,NPRIN,IPRES)
      IF(IPRES.NE.0) THEN
         CALL GPVOLU(0)
      ENDIF
```

All the names quoted here are given as 4-character strings in input and their ASCII equivalent is read into the corresponding variable. The same applies to the user lists of the following section.

3.4   User applications

KEY	N	I	VAR	Short description	COMMON	GINIT
KINE	11	M	IKINE	user flag	/GCKINE/	0
			PKINE	10 user words	/GCKINE/	10^{10}
SETS	20	M	LSETS	user words for detector sets	/GCLIST/	Blank
STAT	20	M	LSTAT	user words to control statistics	/GCLIST/	Blank
PLOT	20	M	LPLOT	user words to control plots	/GCLIST/	Blank
GEOM	20	M	LGEOM	user words to control geometry setup	/GCLIST/	Blank
VIEW	20	M	LVIEW	user words to control view banks	/GCLIST/	Blank

See note in the previous section on the use of these data records.

3.5   Lund event generation

KEY	N	I	VAR	Short description	COMMON	GINIT
LUND	2	M	IFLUND	flavour code (See /GLUNDI/)	/GCLUND/	0
		R	ECLUND	total CMS energy	/GCLUND/	94

3.6   Scan geometry control

The scan geometry has been introduced in GEANT version 3.15 with the idea of developing a general parametrisation scheme. While the scan geometry can already be built, the parametrisation scheme has not yet been developed, so the following data records have to be considered as a *forward compatibility* feature.

KEY	N	I	VAR	Short description	COMMON	GINIT
PCUT	6	M		parametrisation control		
			IPARAM	parametrisation flag	/GCPARM/	0
			PCUTGA	threshold for gammas	/GCPARM/	0
			PCUTEL	threshold for $e^- e^+$	/GCPARM/	0
			PCUTNE	threshold for neutral hadrons	/GCPARM/	0
			PCUTHA	threshold for charged hadrons	/GCPARM/	0
			PCUTMU	threshold for muons	/GCPARM/	0
PNUM	2	I		parametrisation stack size		
			MPSTAK	size of the parametrisation stack	/GCPARM/	1000
			NPGENE	number of pseudo-particles generated	/GCPARM/	20
SCAN	8	M		scan geometry control		
			SCANFL	scan processing flag (LOGICAL)	/GCSCAN/	.FALSE.
			NPHI	number of divisions in ϕ	/GCSCAN/	90
			PHIMIN	minimum value of ϕ	/GCSCAN/	0
			PHIMAX	maximum value of ϕ	/GCSCAN/	360
			NTETA	number of divisions in θ	/GCSCAN/	90
			TETMIN	minimum value of θ	/GCSCAN/	0
			TETMAX	maximum value of θ	/GCSCAN/	180
			MODTET	type of θ division	/GCSCAN/	1
SCAL	32	M	ISLIST	list of volumes to be *scanned*	/GCSCAN/	Blank

KEY	N	I	VAR	Short description	COMMON	GINIT
`SCAP`	6	R		scan parameters		
			`VX`	scan vertex X coordinate	`/GCSCAN/`	0
			`VY`	scan vertex Y coordinate	`/GCSCAN/`	0
			`VZ`	scan vertex Z coordinate	`/GCSCAN/`	0
			`FACTX0`	scale factor for SX0	`/GCSCAN/`	100
			`FACTL`	scale factor for SL	`/GCSCAN/`	1000
			`FACTR`	scale factor for R	`/GCSCAN/`	100

3.7   Landau fluctuations versus δ-rays

In order to avoid double counting between energy loss fluctuations (`ILOSS=2`) and generation of δ-rays `IDRAY=1`, if `ILOSS = 2` the default value for δ-ray generation is set to `0` and it cannot be changed. The different cases are summarised in the table below.

	Full fluctuations `ILOSS = 2 (D)`	Restricted fluctuations `ILOSS = 1 or 3`	No fluctuations `ILOSS = 4`
`IDRAY`	0	1	1
`DCUTE`	`10 TeV`	`CUTELE`	`CUTELE`
`DCUTM`	`10 TeV`	`CUTELE`	`CUTELE`

The reference systems and physical units

1 The `MAster Reference System` (`MARS`)

The kinematic variables of the particles transporter by `GEANT` are always referred to the so-called `MAster Reference System` (`MARS`). This system is implicitly defined as the local reference system of the first volume defined, which contains all the others. This is a Cartesian coordinate system with axis $\hat{x}, \hat{y}, \hat{z}$ where $\hat{z} = \hat{x} \times \hat{y}$. If the axes are labelled (`X`,`Y`,`Z`), then the point P is represented in fig 2.
Figure 2: `GEANT` reference system

Tracking is performed in the `MARS` and the input position for user routines such as the magnetic field routine is given in this system.

2 The local reference systems (`MRS` and `DRS`)

As explained in [`GEOM001`], the setup is described via the definition of an initial volume inside which all the others will be positioned. In `GEANT` terminology, each time a volume has contents, created either via division or by positioning other volumes inside, it is called a `MOTHER`. The volumes contained are called `DAUGHTER`s, and they, in turn, can contain volumes to a depth of 15 levels. This is sometimes referred to as a *Russian doll* geometry.

Every volume defined in `GEANT` has a reference system attached to it (see `GEOM` section). When this volume has contents, this is referred to as the Mother Reference System (`MRS`, with origin in O$_m$). Daughters are positioned inside the mother with respect to the `MRS`. The `MRS` of the first volume defined, containing all the others, is nothing else than the `MARS`.

Each one of the daughters has its own reference system, which is referred to as the Daughter Reference System, or `DRS` with origin in O$_d$.

The transformation of a point from the `MRS` (V$_m$) to the `DRS` (V$_d$), at any level, is performed using a rotation matrix $[R]$ and a translation vector T via the relation :

$$V_d = [R](V_m - T)$$

The components of T are the projections of the vector (O_m, O_d) onto the `MRS` axes. The rotation matrices are computed from the spherical angles of each of the axes of the daughter reference systems (`I`, `II`, `III`) with respect to the mother reference system (`1`, `2`, `3`). The spherical angles Θ and Φ of a direction D are defined as follows :

Θ is the angle formed by the axis 3 and D ($0^\circ < \Theta < 180^\circ$).

Φ is the angle formed by the axis 1 and the projection of D onto the plane defined by the axes 1 and 2 ($0^\circ < \Phi < 360^\circ$).

Examples are given in [`GEOM200`]. The various rotation matrices required for a given setup must be defined by the user during the initialisation stage. A number is assigned to each matrix [`GEOM200`]. The translation vector and the number of the rotation matrix are specified by the user when the volumes are positioned inside their mother [`GEOM110`].

3 Physical units

Unless otherwise specified, the following units are used throughout the program: centimeter, second, kilogauss, GeV, GeV c^{-1} (momentum), GeV c^{-2} (mass) and degree.

Examples of GEANT application

This section contains a skeleton of a standard user program GEXAMP to use the GEANT system. More detailed examples can be found in the standard examples GEXAM1 - 6. The recommended user routines are indicated in bold characters and will be explained more in detail in the following.

```
      PROGRAM GEXAMP                                      CALL GPRINT('MATE',0)
      PARAMETER (NGBANK=50000, NHBOOK=5000)               CALL GPRINT('TMED',0)
      COMMON/GCBANK/Q(NGBANK)                             CALL GPRINT('VOLU',0)
      COMMON/PAWC  /H(NHBOOK)                   C-->  Book histograms
C-->  Initialises  HBOOK and  GEANT memory              END
      CALL GZEBRA( NGBANK)                      *-----------------------------------------------
      CALL HLIMIT(-NHBOOK)                            SUBROUTINE  UGEOM
C-->  Open graphics system                      C-->  Defines material, tracking media
      CALL HPLINT(0)                            C-->  and geometry.
      CALL IGMETA(8,0)                          C-->  Close geometry banks.
C-->   GEANT initialisation                            CALL GGCLOS
      CALL  UGINIT                                      END
C-->  Start events processing                   *-----------------------------------------------
      CALL GRUN                                        SUBROUTINE  GUKINE

C-->  Save permanent data structures                   CALL GLAST
          CALL GRFILE(2,'mysave.dat','NO')       C-->  Close  HIGZ/GKS file
      ENDIF                                            CALL IGEND
C-->  Print banks                                      END
```

1   Notes

- Whenever possible GEANT makes use of the ZEBRA store for large data structures. This allows it to adapt the size of the program data portion to the size of the problem. The total amount of space required depends on the application. GEANT can run with as little as 50,000 words or less, but for large detectors it is not uncommon to declare stores of several million

words. The call to `GZEBRA` initialises the common `/GCBANK/` to receive the `GEANT` data structures. This call is necessary before any other routine of the `GEANT` system is called.

- The call to `HLIMIT` initialises the `ZEBRA` system to use the `/PAWC/` common block for the `HBOOK` histogram package. The size of the common depends on the number and size of the plot requested. The `ZEBRA` system must be initialised only once, and the negative argument to `HLIMIT` prevents a second initialisation of the system. The `HLIMIT` call has to be placed **after** the call to `GZEBRA` and the argument has to be the dimension of the `/PAWC/` common block with a negative sign in front.

- The main program is intended for *batch* applications, while to run the simulation interactively, the interactive main program called `GXINT` should be linked in front of the user code.

- The program shown will require the graphic libraries in the link sequence. Often, for batch production or for small tests, graphics is not needed, and not loading the graphics code makes the program smaller. To avoid loading graphic routines the calls to `IGINIT`, `IGMETA`, `IGEND`, `GDINIT` and `GDEBUG` should be removed.

  If, on the other hand, the user is interested in including the routine `GDEBUG` and in excluding graphics at the same time, then the following routine should be included in the code:

  ```
  SUBROUTINE GDCXYZ
  ENTRY IGSA
  ENTRY GDTRAK
  END
  ```

  which will avoid every reference to the graphics routines from `GDEBUG`.

- The user code to define the *tracking media* and the geometry of the setup should be inside the routine `UGEOM`. The pre-initialised data structured can be read from disk, but it is recommended to call `GPHYSI` in any case, to initialise the cross-section tables. An example of a full material, geometry and detector design is given below and has been extracted from the example `GEXAM3`. Here only major calls are shown, the redundant parts can be found in the source code of `UGEOM` in `GEXAM3`.

  The example shows the basic concept in `GEANT`. First material parameters are defining the properities of a detector material calling the subroutine `GSMATE`. Here in addition to the 16 predefined materials, the material definition of Calcium is examplary shown. More information towards the predefined materials and further use of material definition routines can be found in the section `CONS001 - CONS101`. Then tracking parameters are associated to the materials, defining a so called tracking medium. Each `GEANT` volume must be associated to an existing tracking medium. Here in the example the tracking medium `'TARGET'` is defined to exist of Calcium.

  In the example shown below several detector volumes are defined using the subroutine `GSVOLU`. The defined volume have associated parameters of name, shape, tracking medium and shape parameters. In this example the volume `'TGT '` consists of the previously defined tracking medium `'TARGET'`.The volumes (and if necessary identical copies of them) are then positioned according to the detector geometry. The volumes are positioned on the same level, or inside each other. By setting the parameter `ONLY` or `MANY` in the call of `GSPOS` the user has the opportunity to tell either `GEANT` the logical volume structure or to apply boolean operations (cutting, joining and intersection) between two positioned volumes. More information about the concept in defining volumes and positioning can be retrieved from the section `GEOM`.

  Finally the user is required to classify into sets all sensitive detectors (defined as those volume defined as detector via `GSDET` and other related routines, for which he wants to store hits in the hit data structure `JHITS`.

```
      SUBROUTINE  UGEOM                          +     ('CAVE','BOX ',1,CAVPAR,3,ICAVE)

```

- It is convenient to store the input data records (see [BASE040]) in an auxiliary file (gcards.dat in the example). This allows to have a standard input file and to overwrite selected input data records as needed. If, for instance, the standard gcards.dat file contains the record TRIG 1000 and a short test run is requested this can be obtained with the following input:

```
READ 4
TRIG 10
STOP
```

  the first line instructs FFREAD to open and process the file connected with logical unit 4, and the second line (re-)defines the number of events to be processed. The STOP command ends the FFREAD processing of the input.

- In the above example the common blocks have not been expanded in the code. The notation used is the one of the PATCHY/CMZ [8, 9] code management systems. These products, among other things, can run as pre-processors, replacing the +SEQ, ... instructions with the corresponding code fragments. Users are strongly recommended to use these systems to include GEANT common blocks in their code.

  Long experience in supporting GEANT users has shown that, as the user program grows, typing errors in the insertion of the common blocks *by hand* become very common, but difficult to find. The investment needed to learn a code management system at the user level is usually negligible compared with the time and energy needed in hunting a problem introduced by a mistyped common.

The system initialisation routines

CALL **GZEBRA**   (NZ)

Initialises the ZEBRA memory manager to use the common /GCBANK/ to store the GEANT data structures.

NZ   (INTEGER) size of the /GCBANK/ common as it is dimensioned in the main program.

The size of the dynamic memory is set to NZ-30. The common /GCBANK/ must be dimensioned in the main program. ZEBRA [8] must be initialised only once. The call to the HBOOK initialisation routine HLIMIT tries to initialise ZEBRA as well, and this will cause a program abort. To avoid this, HLIMIT must be called **after** GZEBRA and its argument must be a negative number whose absolute value is the size of the /PAWC/ common containing the histograms. This is shown in the example of main program given in [BASE100].

CALL **GINIT**

Presets labelled common block variables to default values. See [ZZZZ010] for more information.

CALL **GFFGO**

Reads a set of data records via the FFREAD package. See [BASE040] for more information on the possible data records. GFFGO must be called after GINIT.

CALL **GZINIT**

Initialises the ZEBRA permanent data structures in division 2 of the GEANT main store in common /GCBANK/. Creates the user long term division (index IXCONS) (minimum size 2000, maximum size 8*NZEBRA/10). The ZEBRA division IXDIV is reserved for the event data structures and the division IXCONS for the initialisation data structures. Allocates 5200 words of working space. Initialises the link areas and a default run header bank JRUNG [BASE299]. Defines banks format for I/O. GZINIT must be called after GFFGO.

A layout of the dynamic store is shown in fig 3.

/GCBANK/

Fence	Working space	Reserve area	Event division IXDIV	Constant division IXCONS	System division
Figure 3: Layout of the dynamic store

CALL **GDINIT**

This routine initialises the GEANT drawing package [DRAW001] and it has to be called before any other graphic routine. GEANT uses the CERN-developed HIGZ [1] graphic library, and this has to be initialised before the call to GDINIT. In the example given in [BASE100] the routines IGINIT and IGMETA are used. Alternatively, the routine HPLINT from HPLOT [7] can be used. This routine calls the appropriate procedures from HIGZ to initialise the underlaying graphics system. At the moment HIGZ can use several flavours of GKS [2, 3, 4] and X11 and it is available on all machines where the CERN Program Library has been installed.

CALL **GPHYSI**

Completes the data structure JMATE, (see [PHYS100]) calculating the cross-section and stopping power tables.

CALL **GBHSTA**

Initialises the standard histograms requested by the user via the data record HSTA. The following histogram keywords may be used :

`TIME`	time per event;
`SIZE`	size of division `IXDIV` per event;
`MULT`	total number of tracks per event;
`NTRA`	number of *long life* tracks per event;
`STAK`	maximum stack size per event.

`GBHSTA` should be called after `GFFGO`.

`CALL` **GGCLOS**

This routine has to be called at the end of the definition of the geometry by the user, after thal all volumes have been defined and positioned and all detectors defined. Failure to call this routine will prevent the `GEANT` system from working correctly. Main tasks of this routine are:

- close the geometry package;
- complete the `JVOLUM` data structure;
- process the detector definition provided by the user;
- prepare the tables for the tracking speed optimisation requested by the user via the `GSORD` routine or the `OPTI` data record.

Steering routines for event processing

`CALL` **GRUN**

Main routine to control a run of events. The following flow chart is only valid for the *batch* execution mode. For interactive applications, see section `XINT`. A schematic description of the routine is shown in fig. 4.
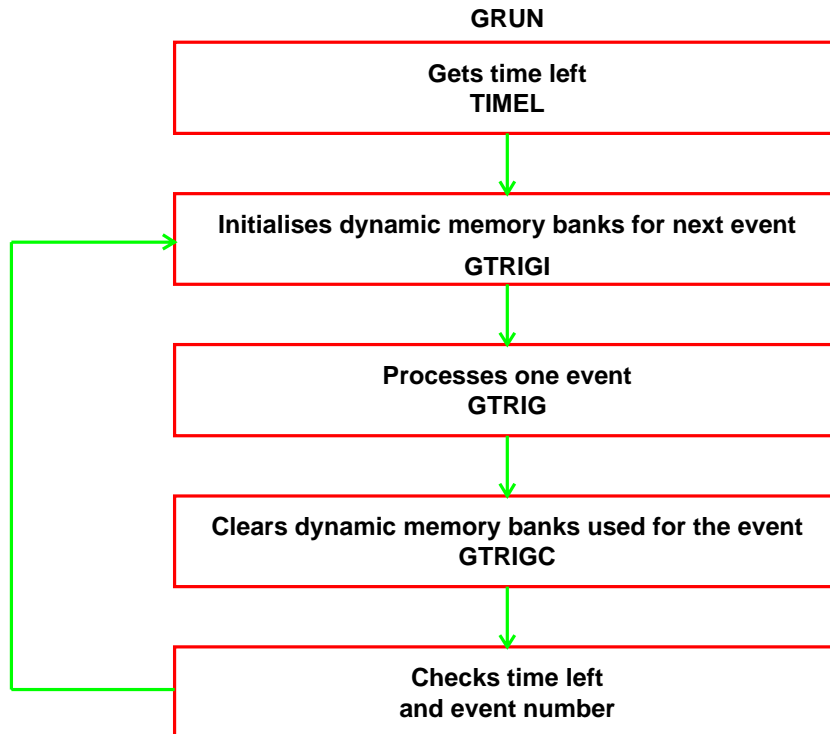

Figure 4: Flow of the `GRUN` routine.

`CALL` **GTRIGI**

Initialisation routine for event processing:

- resets to 0 the flag `IEOTRI` in `/GCFLAG/` and the counters `NTRACK` and `NVERTX` in `/GCNUM/`;
- sets the debug flag `IDEBUG` in `/GCFLAG/` to the value required for the current event;
- creates a default header bank `JHEAD` for current event `[BASE299]`;
- prints the sequence number, the event number and the random number generator seeds, under control of the flag `ITEST` (data record `DEBU`).

`CALL` **GTRIG**

Steering routine to process one event (trigger). A schematic description of the routine is shown in fig. 5.

Default routines provided by `GEANT` are dummy.

`CALL` **GTRIGC**

The event division `IXDIV` is cleared. The space used by the current event may be used by the next one.

GTRIG

Storing and retrieving `JRUNG` and `JHEAD` information

```
    CALL GSRUNG   (NUBUF,UBUF,IADR*)
```

`NUBUF`   (`INTEGER`) number of user words;
`UBUF`   (`REAL`) array of user words;
`IADR`   (`INTEGER`) position where information is stored in the user bank of the `JRUNG` structure.

This routine stores the first `NUBUF` words of array `BUF` in the user bank attached to the structure `JRUNG` (see [`BASE299`]), starting at location `IADR+1`. On exit `IADR` is set to `IADR+NUBUF`, allowing subsequent filling. This allows effectively to *add* information to the current `JRUNG` bank, whether or not it has already an user buffer.

```
    CALL GFRUNG   (NWRUNG*,IRUNG*,NUBUF*,UBUF*)
```

`NWRUNG`   (`INTEGER`) number of words in `JRUNG` bank;
`IRUNG`   (`REAL`) content of `JRUNG` bank;
`NUBUF`   (`INTEGER`) number of user words;
`UBUF`   (`REAL`) array of user words;

This routine retrieves the content of the `JRUNG` bank and of the user information added, if any.

```
    CALL GPRUNG
```

This routine prints the content of the `JRUNG` bank and of the user information added, if any.

```
    CALL GSHEAD   (NUBUF,UBUF,IADR*)
```

`NUBUF`   (`INTEGER`) number of user words;
`UBUF`   (`REAL`) array of user words;
`IADR`   (`INTEGER`) position where information is stored in the user bank of the `JHEAD` structure.

This routine stores the first `NUBUF` words of array `BUF` in the user bank attached to the structure `JHEAD` (see [`BASE299`]), starting at location `IADR+1`. On exit `IADR` is set to `IADR+NUBUF`, allowing subsequent filling. This allows effectively to *add* information to the current `JHEAD` bank, whether or not it has already an user buffer.

```
    CALL GFHEAD   (NWHEAD*,IHEAD*,NUBUF*,UBUF*)
```

`NWHEAD`   (`INTEGER`) number of words in `JHEAD` bank;
`IHEAD`   (`REAL`) content of `JHEAD` bank;
`NUBUF`   (`INTEGER`) number of user words;
`UBUF`   (`REAL`) array of user words;

This routine retrieves the content of the `JHEAD` bank and of the user information added, if any.

```
    CALL GPHEAD
```

This routine prints the content of the `JHEAD` bank and of the user information added, if any.

The banks JRUNG and JHEAD

Run bank `JRUNG`: 1 user link, 30 data words

                                    of the event
       +5 ...10)                    Reserved for user applications
```

Example of user termination routine

```
      SUBROUTINE UGLAST
*
+SEQ,GCLIST
*
*       Call standard GEANT termination routine
      CALL GLAST
*
*       Terminate graphics
      CALL HPLEND
*
*       Close I/O buffers
      IF(NGET .NE. 0 .OR. NSAVE .NE. 0) CALL GCLOSE(0,IER)
*
*       Print histograms
      CALL HISTDO
*
      END
```

`CALL` **GLAST**

Standard `GEANT` termination routine:

- computes and prints the processing time per event;

- calls `MZEND` to print the statistics relative to the current run;

- if the structure `JGSTAT` has been initialised, calls `GPSTAT [GEOM700]`.

Debugging facilities

The flags `IDEBUG`, `ITEST` and `ISWIT(1-10)` are available to in the common `/GCFLAG/` for debug control `[ZZZZ010]`. The array `ISWIT` is filled through the data record `SWIT`. Some flags are used by `GHEISHA [PHYS510]` and by the routine `GDEBUG`.

The flag `IDEBUG` is set to 1 in `GTRIGI` for the events with sequence number from `IDEMIN` to `IDEMAX`, as specified by the user on the data record `DEBU`. If `IDEMIN` is negative, debug is activated also in the initialisation phase.

The flag `ITEST`, set by the user via the data record `DEBU`, is also used by `GTRIGI`. The sequence number, the event number and the random numbers seeds are printed at the beginning of each event every `ITEST` from `IDEMIN` to `IDEMAX`.

1   Debug of data structures

The contents of the data structures can be dumped by the routine

    CALL **GPRINT**   (CHNAME,NUMB)

`CHNAME`   (`CHARACTER*4`) name of a top level data structure;
`NUMB`   (`INTEGER`) number of the substructure to be printed, 0 for all.

Examples

- `CALL GPRINT('KINE',0)` prints all banks `JKINE`;
- `CALL GPRINT('KINE',8)` prints `JKINE` bank for track 8;
- `CALL GPRINT('VOLU',0)` prints all existing volumes.

The following names are recognised:

        DIGI,HITS,KINE,MATE,VOLU,ROTM,SETS,TMED,PART,VERT,JXYZ

`GPRINT` calls selectively the routines:

        GPDIGI('*','*') GPHITS('*','*') GPKINE(NUMB)   GPMATE(NUMB)
        GPVOLU(NUMB)   GPROTM(NUMB)   GPSETS('*','*') GPTMED(NUMB)
        GPPART(NUMB)   GPVERT(NUMB)   GPJXYZ(NUMB)

These routines can be called directly by the user. In case of `SETS`, `HITS` and `DIGI` the content of all detectors of all sets will be printed, so `NUMB` is irrelevant.

2   Debug of events

The development of an event can be followed via the routine:

    CALL **GDEBUG**

which operates under the control of the `ISWIT` array. It is the user responsibility to call this routine from `GUSTEP`. If the `DEBUG` flag is active, the routine will perform as follows:

`ISWIT(1)`

      2   the content of the temporary stack for secondaries in the common `/GCKING/` is printed;

`ISWIT(2)`

      1   the current point of the track is stored in the `JDXYZ` bank via the routine `GSXYZ`;
      2   the current information on the track is printed via the routine `GPCXYZ`;
      3   the current step is drawn via the routine `GDCXYZ`;
      4   the current point of the track is stored in the `JDXYZ` bank via the routine `GSXYZ`. When the particle stops the track is drawn via the routine `GDTRAK` and the space occupied by the track in the structure `JDXYZ` released;

`ISWIT(3)`

      1   the current point of the track is stored in the `JDXYZ` bank via the routine `GSXYZ`.

Utility Routines

CALL **GLOOK**   (CHNAME,IVECT,N,ILOOK*)

CHNAME   (CHARACTER*4) variable containing the name to be searched for in IVECT;
IVECT   (INTEGER) array containing the ASCII code of the names among which NAME is searched. The names are stored 4
            characters per word;
N   (INTEGER) number of items in IVECT;
ILOOK   (INTEGER) position in IVECT where NAME has been found, 0 if not found.

This routine is very useful when searching for a string stored in a ZEBRA bank. For instance to find the position of the 'CRYS'
volume in the volume bank, the following piece of code could be written:

```
+SEQ,GCBANK.
+SEQ,GCNUM.
    .
    .
    .
    CALL GLOOK('CRYS',IQ(JVOLUM+1),NVOLUM,IVO)
    IF(IVO.GT.0) THEN
        JVO = LQ(JVOLUM-IVO)
    ELSE
        JVO = 0
    ENDIF
```

JVO, if different from 0, is the pointer to the data bank containing the information relative to the volume 'CRYS'.

CALL **GEVKEV**   (EGEV,ENERU*,CHUNIT*)

EGEV   (REAL) input, energy in GeV;
ENERU   (REAL) output, energy in the new unit;
CHUNIT   (CHARACTER*4) unit in which the energy has been converted.

This subroutine converts the input energy in GeV to a unit in which $1 \leq E \leq 999$. CHUNIT contains the new unit. The following
piece of code illustrates the use of GEVKEV:

```
+SEQ,GCTRAK.
    CHARACTER*4 CHUNIT
    .
    .
    .
    CALL GEVKEV(DESTEP, DE, CHUNIT)
    WRITE(6,10000) DE, CHUNIT
10000 FORMAT(' The energy loss in this step is ',F7.2,A)
```

Documentation :

The random number generator

CALL **GRNDM**   (VEC*,LEN)

VEC   (REAL) vector containing the generated random number;
LEN   (INTEGER) number of random numbers to generate.

GRNDM generates a sequence of uniformly distributed random numbers in the interval (0,1). The numbers are returned in a vector. The code is a copy of the CERN Program Library routine RANECU [16, 17] (entry V114).

Several independent sequences can be defined and used. Each sequence **must** be initialised by the user, otherwise the result is unpredictable. Two integer seeds are used to initialise a sequence. Not all pairs of integers define a good random sequence or one which is independent from others. Sections of the same random sequence can be defined as independent sequences. The period of the generator is $2^{60} \approx 10^{18}$. A generation has been performed in order to provide the seeds to start any of the generated sections. There are 215 possible seed pairs and they are all 10^9 numbers apart. Thus a sequence started from one of the seed pairs, after 10^9 numbers will start generating the next one.

CALL **GRNDMQ**   (ISEED1,ISEED2,ISEQ,CHOPT)

ISEED1   (INTEGER) first seed of the sequence;
ISEED2   (INTEGER) second seed of the sequence;
ISEQ   (INTEGER) number of the independent sequence of random numbers referred to by this call. If ISEQ≤0, then the last valid sequence used will be addressed either for a save or a store. In case the option 'G' is specified, on output the variable will contain the sequence actually used;
CHOPT   (CHARACTER*(*)) the action to be taken:
             ' '   if 1≤ISEQ≤215, sequence number ISEQ will be initialised with the seeds of the pre-computed independent sequence ISEQ.
                     If ISEQ≤0 or ISEQ>215, sequence number 1 will be initialised with the default seeds. ISEED1 and ISEED2 are ignored;
             'G'   get the present status of the generator: the two integer seeds ISEED1 and ISEED2 will be returned for sequence ISEQ;
             'S'   set the status of the generator. The two integer seeds ISEED1 and ISEED2 will be used to restart the generator for sequence ISEQ.
             'SH'   the same action as for 'S' and store the two integer seeds ISEED1 and ISEED2 in the event header bank.
             'Q'   Get the pre-generated seeds for ISEQ (1≤ISEQ≤215). There are 215 pre-generated sequences each one will generate 10^9 numbers before reproducing the following one.

Initialises the random number generator.

VALUE = **GARNDM**   (DUMMY)

DUMMY   (REAL) dummy parameter, ignored;

Returns a random number r distributed as e^{-x}. $r = -\ln(\eta)$ where η is a random number extracted by GRNDM.

CALL **GPOISS**   (AMVEC,NPVEC*,LEN)

AMVEC   (REAL) array of length LEN containing the average values of the Poisson distributions requested;
NPVEC   (INTEGER) array of length LEN containing the random numbers: NPVEC(I) is a random number with a Poisson distribution of average AMVEC(I);
LEN   (INTEGER) number of random numbers requested.

This routine extracts integer random numbers according to the Poisson distribution. Given a Poisson distribution of average $\lambda \leq 16$ and r uniformly distributed between 0 and 1, the method used is the following:

1. let $P = \exp(-\lambda)$, $N = 0$ and $S = P$;
2. if $r \leq S$ accept N;
3. let $N = N + 1$, $P = P\lambda/N$, $S = S + P$ and go back to 2;

If $\lambda > 16$, a gaussian distribution with average λ and $\sigma = \sqrt{\lambda}$ is generated.

Introduction to the section `CONS`

</div>

1   Introduction

The setup where the particles are transported is represented by a structure of geometrical volumes. Each volume is filled with matter (which can have the properties of the vacuum in case of it contains no matter).

The matter composing the volumes is described via two sets of attributes. The first set is relative to the nature of the *material* composing the volume, and contains information such as the atomic number, the atomic weight, the density and so on (see the description of the routine `GSMATE` in this section for more information).

The second set of attributes is relevant to the process of particle transport and they define a so-called *tracking medium*. These are parameters such as the material composing the volume, the magnetic field, the required tracking precision, the maximum energy that can be lost in one step and so on (see the description of the routine `GSTMED` in this section for more information).

Each tracking medium refers to a material via a *material number* which is assigned by the user. Different tracking media can, with some limitation, refer to the same material.

Each volume is filled by a tracking medium identified by a *medium number*. Different volumes may have the same medium number (see `[GEOM]`).

The transport of particles through a setup (`[TRAK]`) requires access to data which describe:

- the geometry of the setup;

- the *material* and *tracking medium* parameters;

- the particle properties.

The section `[CONS]` contains the routines for the storage and retrieval of information related to materials, tracking media and the particles.

Important note: many entities in `GEANT` are user-defined via a subroutine call. One of the arguments of this subroutine is a integer number which identifies the entity. Examples are materials, tracking media, particles and so on. It can be tempting, for booking purposes, to use very large numbers. For instance, in a large detector, the number of all the materials in the hadronic calorimeter could be $1001 \leq I \leq 2000$. Even if these conventions are very handy, they can introduce a performance penalty.

For reasons of speed, the number provided by the user is used directly as the number of the link in the `ZEBRA` data structure indicating where to store the pointer to the bank containing the information on the entity. `ZEBRA` pointers are contiguous. Defining an object with a user number of 1000 forces `ZEBRA` to allow space for 1000 links. This entails a loss of space (999 words), but much worse than that, induces `ZEBRA` to believe that there are in fact 999 more banks. At every operation which causes a *relocation* of banks, `ZEBRA` will check all the possible links, which can be very time consuming.

So values of user-defined entities must be kept as small as possible and contiguous. In large applications one could write a routine which returns the next free number to be allocated, which can then be stored in a variable and always referenced symbolically, freeing the user from the need to define ranges. As an example we give here a function performing this operation for the material number:

```
      FUNCTION NEXTMA()
+SEQ, GCBANK
      IF(JMATE.LE.0) THEN
```

```
            NEXTMA = 1
       ELSE
            DO 10 IMAT = 1, IQ(JMATE-2)
                 IF(LQ(JMATE-IMAT).EQ.0) GOTO 20
  10        CONTINUE
  20        NEXTMA = IMAT
       ENDIF
       END
```

2 Materials

The material constants are stored in the data structure `JMATE` via the routine `GSMATE` and can be retrieved via the routine `GFMATE` and printed via the routine `GPMATE`. The routine `GMATE` calls repeatedly the routine `GSMATE` to define a standard set of materials, but its use is not mandatory. Mixtures of basic materials, compounds or molecules with atoms from different basic materials, may also be defined and their characteristics are stored in the structure `JMATE`, through calls to the routine `GSMIXT`. Mixtures of compounds are allowed.

Quantities such as energy loss and cross-section tables (see `[PHYS]`), computed during the initialisation of the program are stored in the structure `JMATE`. These can be accessed through the routine `GFTMAT` and plotted or printed through the routines `GPLMAT` and `GPRMAT` respectively.

3 Tracking media

The tracking medium parameters are stored in the data structure `JTMED` by the routine `GSTMED`. Details about these parameters are given in `[TRAK]`. They can be accessed with the routine `GFTMED` and printed with the routine `GPTMED`.

The correctness of the transport process and thus the reliability of the results obtained with `GEANT` depend critically on the values of the *tracking medium parameters*. To help the user, most of the parameters are recalculated by default by `GEANT` irrespective of the value assigned by the user. Advanced users can control the value of the parameters thus bypassing the automatic computation. See the description of the routine `GSTMED` for more information.

The tracking thresholds, and other parameters and flags that control the physics processes, defined in `GINIT` and possibly modified through the relevant data records, are also stored in the structure `JTMED`. These parameters can be redefined for each tracking medium via the routine `GSTPAR`.

4 Particles

The parameters of the particles transported by `GEANT` are stored in the data structure `JPART` via the routine `GSPART`. The decay properties of particles are defined via the routine `GSDK`. The particle constants can be accessed with the routine `GFPART` and printed with the routine `GPPART`.

The routine `GPART` defines the standard table of particles, branching ratios and decay modes. This routine needs to be called for the `GEANT` system to work properly. `GPART` calls the routine `GSPART` for the particle properties and `GSDK` for the decays for each particle in the standard `GEANT` table. The user may call `GSPART` and `GSDK` to extend or modify the table defined by `GPART`.

Material definition

CALL **GMATE**

Stores the following standard material constants in the data structure [7] `JMATE`.

Material	No.	A	Z	Density	Radiat L
Hydrogen	1	1.010	1.000	0.071	865.000
Deuterium	2	2.010	1.000	0.162	757.000
Helium	3	4.000	2.000	0.125	755.000
Lithium	4	6.940	3.000	0.534	155.000
Beryllium	5	9.010	4.000	1.848	35.300
Carbon	6	12.010	6.000	2.265	18.8
Nitrogen	7	14.010	7.000	0.808	44.500
Neon	8	20.180	10.000	1.207	24.000
Aluminium	9	26.980	13.000	2.700	8.900
Iron	10	55.850	26.000	7.870	1.760
Copper	11	63.540	29.000	8.960	1.430
Tungsten	12	183.850	74.000	19.300	0.350
Lead	13	207.190	82.000	11.350	0.560
Uranium	14	238.030	92.000	18.950	0.320
Air	15	14.610	7.300	1.205×10^{-3}	30423
Vacuum	16	10^{-16}	10^{-16}	10^{-16}	10^{16}

Note: this table provides some material definition with standard properties. Advanced user will want to define their own table of materials, which can be done with the routine `GSMATE`, described below.

CALL **GSMATE**   (IMATE,CHNAMA,A,Z,DENS,RADL,ABSL,UBUF,NWBUF)

Stores the constants for the material `IMATE` in the data structure `JMATE`.

IMATE   (INTEGER) material number;
CHNAMA   (CHARACTER*20) material name;
A   (REAL) atomic weight;
Z   (REAL) atomic number;
DENS   (REAL) density in g cm^{-3};
RADL   (REAL) radiation length in cm;
ABSL   (REAL) absorption length in cm. This parameter is ignored by `GEANT`, but it has been kept in
            the calling sequence for backward compatibility;
UBUF   (REAL) array of `NWBUF` additional user parameters;
NWBUF   (INTEGER) number of user words in `UBUF`.

CALL **GFMATE**   (IMATE,CHNAMA*,A*,Z*,DENS*,RADL*,ABSL*,UBUF*,NWBUF*)

Retrieves the constants of material `IMATE` from the data structure `JMATE`. The parameters are the same as for `GSMATE`.

```
CALL GPMATE  (IMATE)
```

Prints the material constants:

IMATE   (INTEGER) material number. If IMATE=0 then all materials will be printed. If IMATE<0 the
          material number -IMATE will be printed without the header describing the value of the various
          fields.

Retrieve material cross-sections and stopping power

    CALL **GFTMAT** (IMATE,IPART,CHMECA,KDIM,TKIN,VALUE*,PCUT*,IXST*)

Retrieve and **interpolate** the dE/dx and cross-sections tabulated in material banks corresponding to a given array of kinetic energy bins.

IMATE   (INTEGER) material number;
IPART   (INTEGER) particle number;
CHMECA   (CHARACTER*4) name of the mechanism bank to be retrieved;
KDIM   (INTEGER) dimension of the arrays TKIN and VALUE;
TKIN   (REAL) array of kinetic energies in GeV;
VALUE   (REAL) array of energy losses in MeV cm^{-1}, or macroscopic cross sections in cm^{-1};
PCUT   (REAL) array containing the 5 energy thresholds for the material in GeV (CUTGAM, CUTELE, CUTNEU, CUTHAD, CUTMUO);
IXST   (INTEGER) return code:

            0   the table was not filled:
            1   normal return; values are returned into the VALUE array;

The mechanisms have the following conventional name and a code number (IMECA):

HADF (1) total hadronic interaction cross-section according to FLUKA;
INEF (2) hadronic inelastic cross-section according to FLUKA;
ELAF (3) hadronic elastic cross-section according to FLUKA;
NULL (4) unused;
NULL (5) unused;
HADG (6) total hadronic interaction cross-section according to GHEISHA;
INEG (7) hadronic inelastic cross-section according to GHEISHA;
ELAG (8) hadronic elastic cross-section according to GHEISHA;
FISG (9) nuclear fission cross-section according to GHEISHA;
CAPG (10) neutron capture cross-section according to GHEISHA;
LOSS (11) stopping power;
PHOT (12) photoelectric cross-section;
ANNI (13) positron annihilation cross-section;
COMP (14) Compton effect cross-section;
BREM (15) bremsstrahlung cross-section;
PAIR (16) photon and muon direct- e^-e^+ pair cross-section;
DRAY (17) δ-rays cross-section;
PFIS (18) photo-fission cross-section;
RAYL (19) Rayleigh scattering cross-section;
MUNU (20) muon-nuclear interaction cross-section;
RANG (21) range in cm;
STEP (22) maximum step in cm.

Note: Common /GCMULO/ contains an array ELOW(200) (see [CONS199]) with NEK1 kinetic energy values ranging from EKMIN to EKMAX. GPHYSI initialises by default the first 91 locations of ELOW with values of

energy from 10^{-5} GeV (10 keV) to 10^4 GeV (10 TeV) equally spaced on logarithmic scale. This can be controlled by the user via the data record or the interactive command `ERAN` (`[BASE040]`). `ELOW` can be used as the input argument `TKIN`, e.g.:

```
CALL GFTMAT (10, 1,'PHOT',NEK1, ELOW ,VALUE, PCUT, IXST)
```

will return in array `VALUE` the photoelectric cross-section in material number 10.

CALL **GPLMAT** (IMATE,IPART,CHMECA,KDIM,TKIN,IDM)

Plot and **interpolate** the dE/dx and cross-sections tabulated in material banks corresponding to a given array of kinetic energy bins. The mechanisms are the same as the previous routine. If the mechanism name is `'ALL'`, then all the mechanisms will be plotted.

The first five parameters have the same meaning as in the previous routine and:

IDM   (`INTEGER`) treatment of the created histogram(s):

            > 0 fill, print, keep histogram(s);

            $= 0$ fill, print, delete histogram(s);

            < 0 fill, noprint, keep histogram(s).

The result is not returned to the user as is the case in the previous routine but it is put in an `HBOOK` histogram. The `HBOOK` package needs to be initialised by the user via the routine `HLIMIT`, see `[BASE100]` for more information. The histogram identifier is calculated as: `10000*IMATE+100*IPART+IMECA` where `IMECA` is the mechanism code listed above.

CALL **GPRMAT** (IMATE,IPART,CHMECA,KDIM,TKIN)

Print and **interpolate** the dE/dx and cross-sections tabulated in material banks corresponding to a given array of kinetic energy bins. The mechanisms are the same as the previous routine. If the mechanism name is `'ALL'`, then all the cross sections will be printed.

The result is printed in the form of a table.

The five parameters have the same meaning as in the previous routine.

Mixtures and Compounds

```
CALL GSMIXT   (IMATE,NAMATE,A,Z,DENS,NLMAT,WMAT*)
```

Defines mixture or compound `IMATE` as composed by `NLMAT` materials defined via the arrays `A`, `Z` and `WMAT`. Mixtures of compounds can also be defined.

IMATE   (`INTEGER`) user material (mixture) number;
NAMATE   (`CHARACTER*20`) mixture name;
A   (`REAL`) array of atomic weights;
Z   (`REAL`) array of atomic numbers;
DENS   (`REAL`) density in g cm^{-3};
NLMAT   (`INTEGER`) number of elements in the mixture;

> > 0 `WMAT` contains the proportion by weights of each material in the mixture;
> < 0 `WMAT` contains the proportion by number of atoms of each kind, the content of `WMAT` in output is changed to contain the relative weights;

Method

For a compound (`NLMAT` < 0), the *molecular* weight and charge are:

$$A_{mol} = \sum_i n_i A_i \qquad\qquad Z_{mol} = \sum_i n_i Z_i$$

where n_i = `WMAT(I)` is the number of atoms of the ith component of the molecule. In this case the proportion by weight is:

$$p_i = \frac{n_i A_i}{A_{mol}}$$

where p_i = `WMAT(I)` in output. From the relative weights, `GSMIXT` works out the effective atomic weight and atomic number according to the following formulas:

$$A_{eff} = \sum_i p_i A_i \qquad\qquad Z_{eff} = \sum_i p_i Z_i$$

which are stored in the `JMATE` data structure `[CONS199]` together with the radiation length.

The radiation length is computed according to the EGS manual [12], formula 268 (37), for an element:

$$\frac{1}{\rho\, X_0} = 4\alpha r_0^2 N_{Av} \frac{1}{A} Z(Z + \xi(Z)) \left[\ln\frac{183}{Z^{1/3}} - F_c(Z)\right]$$

where

X_0 radiation length (in cm);
ρ density (in g cm^{-3});
α fine structure constant;
r classical electron radius (in cm);
N_{Av} Avogadro's number;

A atomic weight;

Z atomic number;

$F_c(Z)$ Coulomb correction function.

$$F_c(Z) = (\alpha Z)^2 \left[\frac{1}{1 + (\alpha Z)^2} + 0.20206 - 0.0369(\alpha Z)^2 + 0.0083(\alpha Z)^4 - 0.0020(\alpha Z)^6 \right]$$

$$\xi(Z) = \frac{\ln \frac{1440}{Z^{2/3}}}{\ln \frac{183}{Z^{1/3}} - F_c(Z)}$$

for a compound or mixture:

$$\frac{1}{\rho X_0} = \sum_i \frac{p_i}{\rho_i X_{0i}}$$

where p_i is the proportion by weight of the ith element. For more information on the organisation of the data in memory see [CONS199].

The effective absorption length λ is defined as the interaction length of a 5GeV pion in the material:

$$\frac{1}{\lambda} = \sum_i \frac{p_i}{\lambda_i} \qquad\qquad \frac{1}{\lambda_i} = \frac{\sigma_i^\pi (5GeV) N_{Av}}{A_i} \quad g^{-1} \; cm^2$$

Once this value has been determined, an effective hadronic atomic weight (A_{h-eff}) is calculated by the routine GHMIX [3] and stored in the data structure.

## The Material data structure `JMATE`

Figure 6: `JMA = LQ(JMATE-IMATE)` pointer to material `IMATE`

When the subroutine GPHYSI is called at initialisation time the following substructure is created for each material whose number is refered to by any of the user defined tracking media.

Note: The energy losses are stored in $GeV \ cm^{-1}$. The inverse of the macroscopic cross-section (i.e. the mean free path, in cm), is stored instead of the cross-section, to speed up the calculation of the distance to the next interaction point.
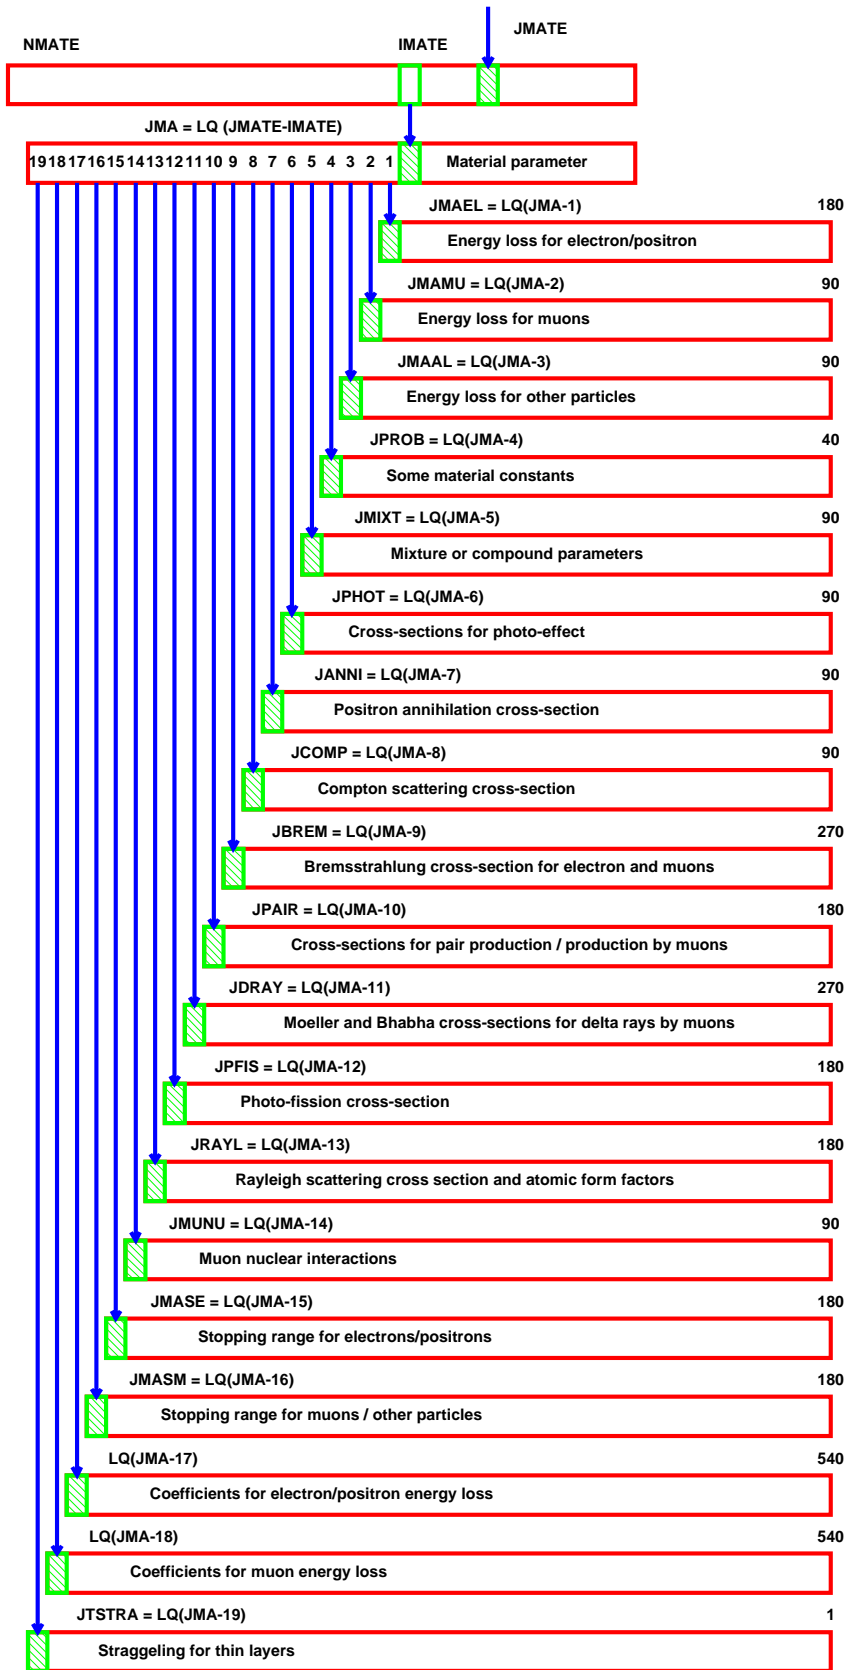

Figure 7: Material data structure

1 Energy binning

IDECAD	Bin number	Energy range IEKBIN
1	1 → 10	10 KeV → 79.43 KeV
2	11 → 20	100 KeV → 794.3 KeV
3	21 → 30	1 MeV → 7.943 MeV
4	31 → 40	10 MeV → 79.43 MeV
5	41 → 50	100 MeV → 794.3 MeV
6	51 → 60	1 GeV → 7.943 GeV
7	61 → 70	10 GeV → 79.43 GeV
8	71 → 80	100 GeV → 794.3 GeV
9	81 → 90	1 TeV → 7.943 TeV

The values of the bins are kept in the array ELOW(90) in /GCMULO/ :

$$\text{ELOW}(i) = 10^{\frac{i-1}{10} - 5}[\text{GeV}]$$

2 Energy loss for electrons and positrons

Words 1 to 90, for electrons: DE/DX = Ionisation (Moller) +brems.

Words 91 to 180, for positrons: DE/DX = Ionisation (Bhabha) +brems. [PHYS 330, 340].

3 Energy loss for muons

DE/DX = Ionisation +brems. +Direct e^+e^- production +Nuclear interacti on [PHYS 430, 440, 450].

4 Energy loss for other charged particles

DE/DX = Ionisation

The values are computed for a proton (mass Mp). For any other particle with mass M and kinetic energy T, one has to compute the equivalent proton kinetic energy as T*Mp/M and look at the corresponding energy binning [PHYS 430].

5 Some material constants

Various constants which are material dependent and needed to compute the cross-sections.

See routine GPROBI.

6 Mixture and compound parameters

Words 1 to 4*NLM where NLM is the number of mixture or compound components [CONS110].

7 Photo-electric effect. Muon nuclear interaction

As the photo-electric effect vanishes at high energies whereas the muon nuclear interaction cross-section is null at low energies, the two effects are stored within the same bank in order to save space.

From 10 KeV to 50 MeV : Photo-electric effect mean free path [PHYS 230] From 1 GeV to 10 TeV : Muon nuclear interaction mean free path [PHYS 460].

8 Positron annihilation

[PHYS 350].

9 Compton scattering

[PHYS 220].

10 Bremsstrahlung for electrons and muons

Words 1 to 90, mean free path for electrons [PHYS 340] Words 91 to 180, mean free path for muons [PHYS 440].

11 Pair production by gammas and muons

Words 1 to 90, for gammas [PHYS 210]. Words 91 to 180, for muons [PHYS 450].

12 Delta ray production by electrons and muons

Words 1 to 90, for $e^- e^- \rightarrow e^- e^-$ [PHYS 330].
Words 91 to 180, for $e^+ e^- \rightarrow e^+ e^-$ [PHYS 330]
Words 181 to 270, for $e^- \rightarrow e^-$ [PHYS 430].

13 Photo-fission

Only for material with atomic number A>200 [PHYS 240].

Tracking medium parameters

Description of the routines

```
CALL GSTMED (ITMED,NATMED,NMAT,ISVOL,IFIELD,FIELDM,TMAXFD,STEMAX,
             DEEMAX,EPSIL,STMIN,UBUF,NWBUF)
```

This routine associates a set of tracking parameters to a material, defining a so-called *tracking medium*. Every `GEANT` volume must be associated to an existing tracking medium. The routine stores the parameters of the tracking medium `ITMED` in the data structure `JTMED`.

ITMED   (`INTEGER`) tracking medium number;

NATMED   (`CHARACTER*20`) tracking medium name;

NMAT   (`INTEGER`) material number corresponding to `ITMED`;

ISVOL   (`INTEGER`) *sensitivity* flag (see later):

          ≤ 0 not a sensitive volume;

          >0 sensitive volume;

IFIELD   (`INTEGER`) magnetic field flag:

          `=0`   no magnetic field;

          `=1`   strongly inhomogeneous magnetic field (returned by the user function `GUFLD`): tracking performed with the Runge-Kutta method by the routine `GRKUTA`;

          `=2`   inhomogeneous magnetic field (returned by the user function `GUFLD`), tracking along a helix performed by the routine `GHELIX`;

          `=3`   uniform magnetic field along the `z` axis of strength `FIELDM`, tracking performed along a helix by the routine `GHELX3`;

FIELDM   (`REAL`) maximum field value (in Kilogauss);

TMAXFD   (`REAL`) maximum angular deviation due to the magnetic field permitted in one step (in degrees);

STEMAX   (`REAL`) maximum step permitted (cm);

DEEMAX   (`REAL`) maximum fractional energy loss in one step ($0 < $ `DEEMAX` ≤ 1);

EPSIL   (`REAL`) boundary crossing precision (cm);

STMIN   (`REAL`) minimum value for the maximum step imposed by energy loss, multiple scattering, Čerenkov or magnetic field effects (cm);

UBUF   (`REAL`) array of `NWBUF` additional user parameters;

NWBUF   (`INTEGER`) number of additional user parameters.

Note: the tracking medium number can in principle be any positive integer from 1 to 65,535. However this number is used directly by `GEANT` as the number of the pointer to the data structure where the information is stored. When a pointer is defined, all pointers from 1 to the one allocated are created, if not already existing. Every time data structures are moved in memory, all the links are potentially scanned for update. This can be time consuming and it can seriously affect performances. So a continuous range of numbers should be used for tracking media.

```
CALL GFTMED (ITMED,NATMED*,NMAT*,ISVOL*,IFIELD*,FIELDM*,TMAXFD*,
             STEMAX*,DEEMAX*,EPSIL*,STMIN*,UBUF*,NWBUF*)
```

Extracts the parameters of the tracking medium `ITMED` from the data structure `JTMED`.

```
     CALL GPTMED  (ITMED)
```

Prints the tracking medium parameters for the given medium.

`ITMED` (`INTEGER`) tracking medium to be printed, all tracking media if `ITMED`=0.

Automatic calculation of the tracking parameters

The results of the simulation depend critically on the choice of the tracking medium parameters. To make of `GEANT` a reliable and consistent predictive tool, the calculation of these parameters has been automated. In a normal GEANT run, the variable `IGAUTO` in common `/GCTRAK/` is set to 1. In this case the following parameters are calculated by the program:

$$\texttt{TMAXFD} \;=\; \begin{cases} 20° & \text{if } \texttt{TMAXFD} \leq 0 \text{ or } \texttt{TMAXFD} > 20 \\ \textit{input value} & \text{if } 0 < \texttt{TMAXFD} \leq 20 \end{cases}$$

$$\texttt{STEMAX} \;=\; \texttt{BIG}(= 10^{10})$$

$$\texttt{DEEMAX} \;=\; \begin{cases} 0.25 & \text{if } \texttt{ISVOL} = 0 \text{ and } X_0 \leq 2cm, \text{ where } X_0 \text{ is the radiation length of} \\ & \text{the material} \\ 0.25 - \dfrac{0.2}{\sqrt{X_0}} & \text{otherwise} \end{cases}$$

$$\texttt{STMIN} \;=\; \begin{cases} \dfrac{2\,R}{\sqrt{X_0}} & \text{if } \texttt{ISVOL} = 0 \\ \dfrac{5\,R}{\sqrt{X_0}} & \text{if } \texttt{ISVOL} \neq 0 \end{cases}$$

where R is the range in cm of an electron of energy `CUTELE`+200keV.

If the `IGAUTO` variable is set to 0 via the `AUTO` data record, then value given by the user for the above parameters is accepted as the true parameter value if > 0, while automatic calculation still takes place in case the input value is negative.

Users are strongly recommended to begin their simulation with the parameters as calculated by `GEANT`. Users who want to modify any of the above parameters must be sure they understand their function in the program and the implications of a change.

The `EPSIL` parameter represents the absolute precision with which the tracking is performed. It has a double meaning. When tracking in magnetic field, `EPSIL` is the minimum distance for which boundaries are checked. A particle nearer than `EPSIL` to the boundary is considered as exiting the current volume. If the end point of the step of a particle in magnetic field is distant less than `EPSIL` along each axis from what would be the end point in absence of magnetic field, then no boundary checking is performed.

In all cases, when a particle is going to reach the boundary of the current volume with the current step, the step length is increased by a quantity (`PREC`, common `/GCTMED/`) which is set to the minimum between $0.1 \times EPSIL$ and 10 micron at the beginning of the tracking. This quantity is recalculated at every step according to the formula:

$$\texttt{PREC} = \max\left[\min\left(\frac{\texttt{EPSIL}}{10}, 10\mu \right), \max\left[|x|, |y|, |z|, S \right) \times \epsilon \right] \tag{1}$$

Where x, y, z are the current coordinates of the particle, S is the length of the track, and ϵ is the assumed machine precision. ϵ (called `EPSMAC` in the program) is initially set to 10^{-6} for 32 bits machines and 10^{-11} for 64 bits machines. During the tracking, every fifth time that a particle tries unsuccessfully to exit from the same volume, the machine precision is multiplied by the number of trials. This accounts for additional losses of precision due to transformation of coordinates and region of the floating point range where the real machine precision is different from the above (this happens in particular on IBM mainframes with 370 floating point number representation).

Special Tracking Parameters

```
CALL GSTPAR  (ITMED,CHPAR,PARVAL)
```

`ITMED`   (`INTEGER`) tracking medium number;
`CHPAR`   (`CHARACTER*4`) character string, name of the variable to be modified;
`PARVAL`   (`REAL`) new value (must be given as a floating point).

Default parameters			Parameter name	Default value

The data structure `JTMED` contains the standard tracking parameters (`CUTS` and flags to control the physics processes) which are used by default for all tracking media. It is possible to redefine individually with

`GSTPAR` any of these parameters for a given tracking medium. For example to change `CUTGAM` to 0.0001 for tracking medium `ITMED`:

$$\texttt{CALL GSTPAR(ITMED,'CUTGAM',0.0001)}$$

For more information on default values for `IDRAY` and `ILOSS` see `[BASE040]`.

The default tracking medium parameters are stored in the bank whose pointer is stored in the `JTMED` variable. In this case in the above table `JTMN = JTMED`. In the case one or more of the above parameters has been modified for a specific tracking medium, the whole parameter set is stored in the next bank of the given trackin medium. In this case `JTMN = LQ(JTM)` in the above table, where `JTM` is the pointer to the bank of the tracking medium, i.e. `JTM = LQ(JTMED-ITMED)`.

Note

At tracking time the parameters above are copied from `JTMN` into the common blocks `/GCCUTS/` and `/GCPHYS/`. `GSTPAR` must be called before `GPHYSI`.

Particle definition

CALL **GPART**

Stores the standard particle constants in the data structure JPART and, through the routine GSDK, their decay modes [CONS310].

Note

It is possible for the user to define more particles or to redefine some characteristics of the particles currently defined in GEANT, but this must be done with extreme care. In particular, the mass and charge of most particles are stored independently in FLUKA, and any change made via GSPART will not affect these values. Removing particles from the list can lead to unpredictable results and it is strongly discouraged.

The user who needs more particles, or wants to partly override the standard values, can do that via the routines GSPART and GSDK.

All data taken from M. Aguilar Benitez [4] and updated with the values of the PDG [5].

    CALL **GSPART**   (IPART,CHNPAR,ITRTYP,AMASS,CHARGE,TLIFE,UB,NWB)

Stores the constants describing the particle. IPART in the data structure JPART.

IPART   (INTEGER) particle number;
CHNPAR   (CHARACTER*20) particle name;
ITRTYP   (INTEGER) type of tracking routine requested:

       1   particle tracked by GTGAMA;
       2   particle tracked by GTELEC;
       3   particle tracked by GTNEUT;
       4   particle tracked by GTHADR;
       5   particle tracked by GTMUON;
       6   geantino tracked by GTNINO;
       7   heavy ion tracked by GTCKOV;
       8   light photon tracked by GTHION;

AMASS   (REAL) particle mass in GeV;
CHARGE   (REAL) particle charge;

```
TLIFE      (REAL) particle life time (in seconds);
UB         (REAL) array of NWB user additional parameters;
NWB        (INTEGER).
```

```
CALL GFPART  (IPART,CHNPAR*,ITRTYP*,AMASS*,CHARGE*,TLIFE*,UB*,NWB*)
```

Extracts the constants describing the particle `IPART` from the data structure `JPART`.

```
CALL GPPART  (IPART)
```

Prints the particle constants for particle `IPART` (for all particles if `IPART=0`).

Branching Ratios and Particle Decay Modes

> CALL **GSDK** (IPART,BRATIO,MODE)

IPART   (INTEGER) GEANT particle number;
BRATIO   (REAL) array of branching ratios in %, maximum 6;
MODE   (INTEGER) array of partial decay modes.

GSDK stores the branching ratios and partial decay modes for two and three body particle decays into the data structure JPART. The decay modes should be coded into the array MODE such that:

$$\text{MODE(I)} = 10^4 \text{ N3} + 10^2 \text{ N2} + \text{N1} \qquad \text{for I=1,}\cdots\text{,6}$$

where:

N1   particle number for decay product 1;
N2   particle number for decay product 2;
N3   particle number for decay product 3 (if any).

It is important to note the following:

- prior to calling GSDK, all parent and secondary particles should have been defined by GSPART;

- if less than six decay modes are defined the remaining elements of BRATIO and MODE must be set to zero.

For a given particle, IPART, the decay parameters are stored into the JPART data structure as follows:

JPA   = LQ(JPART-IPART) pointer to the bank containing the information on the particle IPART;
JDK1   = LQ(JPA-1) pointer to branching ratios bank;
JDK2   = LQ(JPA-2) pointer to decay modes bank;
BR(I)   = Q(JDK1+I) I^{th} branching ratio;
MODE(I)   = IQ(JDK2+I) I^{th} decay mode, where I=1,$\cdots$,6.

When a particle decays during tracking, the routine GDECAY is called. If branching ratios and modes have been stored by GSDK, then GDECAY generates the decay products in the 2- or 3-body phase space. If no branching ratios have been defined by GSDK, the user routine GUDCAY is called, where the user can code special decay modes and branching ratios. All data taken from Aguilar Benitez [4].

Introduction to the Drawing package

1   The drawing package

The drawing package has been designed mainly to visualise:

- detector components;

- the logical tree of detector components;

- the geometrical dimensions;

- particle trajectories

- the hits recorded in the sensitive elements of the detector.

2   Graphics in `GEANT`

The set of routines in the drawing package allows the visualisation of the volumes of the detector. These routines can be called from the user program or interactively via the command interface. The output can be directed onto the screen or to a file. The graphics of `GEANT` is based on the `HIGZ` [1] package. `HIGZ` is a high-level interface between the user program (in this case `GEANT`), `ZEBRA` and a basic graphics library. At the moment of writing, `HIGZ` can use various flavours of the `GKS` [2, 3, 4] graphics system or the `X11` [5] system. A version based on the `PHIGS` [6] system is now being developed at CERN.

3   Graphics functionality of `GEANT`

The graphics capabilities of `GEANT` have been greatly enhanced in the last few revisions of the program. It is now possible to display volumes with hidden lines removed from the drawing. This improves the understanding of complicated objects. It is also possible to *cut* the displayed volumes with various shapes (boxes, cones, tubes and spheres) in order to visualise the internals of a detector element. The surfaces of the volumes drawn can be filled with colour, either solid or shaded according to a scan-line based lighting algorithm. A more sophisticated surface rendering algorithm is now being developed but it will be available only in the next version of the program.

Almost all drawing commands can be executed either by calling a routine from the user application or by issuing a command when running `GEANT` with the standard interactive interface. Several interactive tools (`ZOOM`, `LENS`) have been developed to analyse in detail the various parts of the detectors. The interactive `MOVE` facility allows the rotation, translation and zooming in real time for simple components of the detectors. Some of these commands are only available in the interactive interface. These are described briefly in `[DRAW500]` and more extensively in the `[XINT]` section.

A user interface based on X-Windows and Motif is also available mainly on Unix workstations. Details of this interface are described in `[DRAW510]`.

Various graphical options can be set via the `GSATT` and `GDOPT` routines.

Every detector component can be visualised either in orthonormal projection or in perspective (routines `GDRAW` and `GDRVOL`). Sections of the volumes and of their descendents can be visualised as well (routines `GDRAWX` and `GDRAWC`).

The hierarchical relations of the various volumes which compose the detector can be visualised via the `GDTREE` routine. In the interactive interface the user can select one of the volumes which are nodes of the tree with the mouse, and display the characteristics of the volume and walk up and down the logical tree.

Tracks and hits can be drawn either alone or superimposed on the detector (routines `GDCHIT`, `GDHITS`, `GDAHIT`, `GDXYZ`). It is also possible to draw the tracks while tracking is performed via the routine `GDCXYZ`.

The drawing may be done with hidden-line removal and with shading effects according to the value of the options `HIDE` and `SHAD` (see next section).

Drawing complicated detectors can be a lengthy process even on a fast machine. In particular, when graphics options like hidden line removal or surface shading are requested and many volumes are involved, the complete drawing can take several minutes on the most powerful workstations. To alleviate this problem drawings can be stored in memory in so called *view banks*. The routines involved are `GDOPEN`, `GDCLOS`, `GDSHOW` and `GDELET`, and the corresponding interactive commands (`DOPEN`, `DCLOSE`, `DSHOW`, `DELETE`). These banks can then be redisplayed quickly. They can also be written on disk and read back.

Attributes like colour (`GDCOL`) and line width (`GDLW`) can be globally set for all 2D drawings (i.e. text, vectors, man, etc.); such attributes do not affect the volume attributes that can be set by the `GSATT` routine with `COLO` or `LWID` option.

The user can control some drawing options (`GDOPT`), by selecting, for instance, to have either parallel or perspective projection, either `Y-Z` or `R-Z` projection, etc.

The geometrical dimensions of an existing volume can be changed via the routine `GEDITV`.

Various service routines allow the drawing of the profile of a human figure, the axis, the scale of the dimension of the drawing and so on. These are described in `[DRAW400]`.

4   The shading algorithm

In `GEANT 3.16` a new shading algorithm has been introduced which is 10 to 100 times faster than the algorithm which was implemented in `GEANT 3.15`. In the new algorithm the search for the visible portions of all the faces of every volume is performed in the following steps:

1. the vertices of each face are transformed from the `MARS` to the screen reference system. In this way the dimensions of the face are of the order of magnitude of centimeters.

2. in the screen reference system the face is *filled* with horizontal lines *scan-lines* according to the desired resolution.

3. These lines are then transformed back in the `MARS`, where the hidden line removal technique is used to find their visible portions.

4. The colour luminosity is chosen as a function of the angle between the normal to the surface and the line of view which is considered to be also the line of illumination.

5. The visible portions of the lines are finally transformed into the screen reference system and drawn with the calculated luminosity so that they fill only the visible part of each face.

The resulting picture can be saved into `GEANT` view banks or `HIGZ` picture files.

5   Summary

The best way to initialise the drawing package is to call the `HPLOT` [7] initialisation routine `HPLINT`. This will work independently of the basic graphic package used. The reader should consult the `HPLOT` documentation for more information on this routine. The drawing package is initialised by:

`HPLINT` to initialise the basic graphics package and the `HPLOT` package;
`GDINIT` to initialise the `GEANT` drawing package.

The main drawing routines are:

`GDRAW`   to draw a projection view of the detector – Case 1
`GDRVOL` to draw a projection view of the detector – Case 2
`GDRAWC` to draw a cut view of the detector (along one axis)
`GDRAWX` to draw a cut view of the detector (from any point)
`GDXYZ`   to draw tracks at the end of the event
`GDCXYZ` to draw tracks at tracking time
`GDPART` to draw particle names and track numbers at end of tracks
`GDAHIT` to draw one single hit
`GDHITS` to draw hits for *trajectory* type detectors
`GDCHIT` to draw hits for *calorimeter* type detectors

Routines that show how the detector has been modelled are:

`GDTREE` to draw a picture with the geometrical tree
`GDSPEC` to draw a picture with volume specifications
`GDFSPC` to draw several GDSPEC pictures

Routines that perform control operations on view banks are:

`GDOPEN` to open a given view bank, identified by a view number; in this way we enter in bank mode
`GDCLOS` to close the current view bank, i.e. the last one opened, and restore screen mode
`GDSHOW` to show all graphics information contained in a given view bank
`GDLENS` to scan interactively the drawing contained in the view bank
`GDELET` to delete a given view bank from memory

Routines that allow the visualisation of the detector with hidden line removal are:

`GDCGOB` to create CG objects
`GDCGSL` to create clipping objects
`GDCGCL` to perform boolean operations
`GDCGHI` to insert CG objects in HIDE and WIRE structures of faces
`GDSHIF` to shift in the space a CG object
`GDBOMB` to make the detector explode

Other routines are:

`GDOPT`   to set drawing options
`GDZOOM` to set the zoom parameters
`GDAXIS` to draw the axes of the MARS, oriented according to the current view parameters
`GDSCAL` to draw the current scale
`GDMAN`   to draw a profile of a man within the current scale
`GDRAWT` to draw text, with software characters
`GDRAWV` to draw polylines in 2D user coordinates
`GDHEAD` to draw a frame header
`GDCOL`   to set colour code
`GDLW`   to set line width
`GDCURS` to have an input from the graphics cursor
`GDFR3D` to convert from 3D coordinates (either in MARS or DRS) to 2D user coordinates
`GD3D3D` to convert from 3D MARS coordinates to 3D Projection Reference System coordinates.

The Ray-tracing package

Running interactively under X11, a new visualization tool is provided in `GEANT` 3.21: the ray-tracing package. Based on the new `GEANT` tracking (see `GEOM` and `TRACK`), a set of routines doing light processing is provided to visualize the detectors (useful also to visualize the results of boolean operations). Basically, visible light particles are tracked throughout the detector until when they do not hit the surface of a volume declared not transparent; then, the intersection point is transformed to the screen coordinates and the corresponding pixel is drawn with a computed hue and luminosity.

In case the command (`DOPT RAYT ON`) is executed, the drawings are performed by the `GEANT` ray-tracing; automatically, the color is assigned according to the tracking medium of each volume and the volumes with a density lower/equal than the air are considered transparent; if the option (`USER`) is set (`ON`) (again via the command (`DOPT`)), the user can set color and visibility for the desired volumes via the command (`SATT`), as usual, relatively to the attributes (`COLO`) and (`SEEN`). The resolution can be set via the command (`SATT *` `FILL VALUE`), where (`VALUE`) is the ratio between the number of pixels drawn and 20 (user coordinates). Parallel view and perspective view are possible (`DOPT PROJ PARA/PERS`).

In the first case, we assume that the first mother volume of the tree is a box with dimensions 10000 X 10000 X 10000 cm and the view point (infinetely far) is 5000 cm far from the origin along the Z axis of the user coordinates; in the second case, the distance between the observer and the origin of the world reference system is set in cm by the command (`PERSP NAME VALUE`). Grand-angle or telescopic effects can be achieved changing the scale factors in the command (`DRAW`). (Please, note that in case of perspective views, fixed the distance of the viewer, the zooming factors for the raytracing option must be 8.25 times bigger than the ones used for the `HIDE` options in order to get the same picture). When the final picture does not occupy the full window, mapping the space before tracing can speed up the drawing, but can also produce less precise results; values from 1 to 4 are allowed in the command (`DOPT MAPP VALUE`), the mapping being more precise for increasing (`VALUE`). For (`VALUE` = 0) no mapping is performed (therefore max precision and lowest speed).

The command (`VALCUT`) allows the cutting of the detector by three planes ortogonal to the x,y,z axis. The attribute (`LSTY`) can be set by the command `SATT` for any desired volume and can assume values from 0 to 7. It determines the different light processing to be performed for different materials: 0 = dark-matt, 1 = bright-matt, 2 = plastic, 3 = ceramic, 4 = rough-metals, 5 = shiny-metals, 6 = glass, 7 = mirror.

The detector is assumed to be in the dark, the ambient light luminosity is 0.2 for each basic hue (the saturation is 0.9) and the observer is assumed to have a light source (therefore he will produce parallel light in the case of parallel view and point-like-source light in the case of perspective view). Finally, a second light source can be positioned in the space (with a desired intensity) via the command (`SPOT`).

Drawing a Volume – Case 1

```
CALL GDRAW  (CHNAME,THETA,PHI,PSI,UO,VO,SU,SV)
```

Draws an orthographic parallel projection or a perspective projection of volume `CHNAME` according to the options set via the routine `GDOPT` and all its *visible* descendants (see routine `GSATT` to alter the visibility of a volume) at position `UO,VO` (user coordinates), with the scale factors `SU` and `SV`; the object is seen from `THETA` and `PHI` angles, and the resulting 2D projection is rotated by an angle `PSI` on the screen plane. These parameters, as well as zoom parameters set by `GDZOOM` define the current *view parameters*, and they are copied in the common `/GCDRAW/`. Attributes like colour, surface fill, line width, line style, visibility, etc. can be set by calling the `GSATT` routine for `CHNAME` and its descendants [GEOM 500]. An example of the result of the call:

$$\text{CALL GDRAW('ARM ',40.,40.,0.,nx,ny,0.015,0.015)}$$

is given in fig 8 for various values of the attributes and graphic options.

default drawing   **hidden lines removed**

surface shading   **perspective view**
Figure 8: Examples of use of `GDRAW`

Drawing with hidden line removal and surface fill shading is also possible, but the drawing time may increase substantially for complicated objects.

When using the interactive interface it is possible to *cut* the object to be drawn with *cutting* volumes (command `CVOL`). This is particularly useful to visualise the contents of an object drawn with hidden line

removal. Another feature which is available only interactively is the possibility to draw each decendant of a volume shifted along the axis which goes from the centre of the local coordinate system to the centre of gravity of the descendant itself. This again is useful to improve the visibility of the details of a complicated setup (command `BOMB`). Please see the interactive interface description for more information on this part.

`CHNAME` (`CHARACTER*4`) volume name.

`THETA` (`REAL`) theta angle between the line of sight and the `Z` axis of `MA`ster Reference System (`MARS`).

`PHI` (`REAL`) phi angle between the projection of the line of sight on plane `X Y` and the `X` axis of `MARS`.

`PSI` (`REAL`) psi angle by which the projected image will be rotated on the screen plane.

`UO` (`REAL`) u coordinate on the screen of the volume origin.

`VO` (`REAL`) v coordinate on the screen of the volume origin.

`SU` (`REAL`) scale factor for u coordinates.

`SV` (`REAL`) scale factor for v coordinates.

Drawing a Volume Projection view – Case 2

> CALL **GDRVOL**   (NNAMS,CHNAMS,LNUMBS,NRS,THETA,PHI,PSI,UO,VO,SU,SV)

Draws an orthographic parallel projection or a perspective projection (depending on the option chosen via `GDOPT`) of the volume `CHNAMS(N),LNUMBS(N)` with all its descendants, at the position `UO,VO` (user coordinates), with the scale factors `SU` and `SV`. The object is seen from `THETA` and `PHI` angles, and the resulting 2D projection is also rotated by an angle `PSI` on the screen plane. These parameters, as well as zoom parameters set by `GDZOOM`, define the current *view parameters*, and they are copied in `/GCDRAW/`. Attributes like colour, fill area, line width, line style, visibility, etc. can be set by the `GSATT` routine for `CHNAMS(N)` and or its descendants [`GEOM 500`]. This routine differs from `GDRAW` in the following aspects:

- The object to be drawn is identified by a full path. This gives the possibility of drawing a particular copy or division of a volume, or even a volume that has more than one mother in the geometry tree. `CHNAMS(1),...,CHNAMS(N)` contain the volume names and `LNUMBS(1),...,LNUMBS(N)`, the volume numbers defining the path to go from the top volume to the one to be drawn.

- The object can be drawn either with respect to the `MA`ster Reference System (`NRS=0`) or with respect to its `Da`ugther Reference System (i.e. the Local R.S.); in the first case it is drawn in its position in the real world, while in the second one it is drawn like `GDRAW` would do.

- In this latter case, track and hit points will be drawn with respect to the `DRS` of the volume last drawn by this routine, and not with respect to the `MARS` as is done normally (to reset to the normal case a call with `NRS=0` or `NNAMS=0` is required).

NNAMS   (`INTEGER`) number of elements `levels` in the arrays `CHNAMS`, `LNUMBS`. The bottom volume of this path is also the one that is actually drawn;

CHNAMS   (`CHARACTER*4`) array of volume name (dimensioned at least to `NNAMS`);

LNUMBS   array of volume numbers (dimensioned at least to `NNAMS`);

NRS   reference system used:

       `NRS=0`   to have the volume(s) drawn with respect to the `MARS`

       `NRS≠0`   to have the volume(s) drawn with respect to the `DRS`

THETA θ angle between the line of sight and the Z axis of `MARS`;

PHI ϕ angle between the projection of the line of sight on plane `X Y` and the `X` axis of `MARS`

PSI ψ angle by which the projected image will be rotated on the screen plane

UO   u coordinate on the screen of the volume origin

VO   v coordinate on the screen of the volume origin

SU   scale factor for u coordinates

SV   scale factor for v coordinates

Two examples of use of `GDRVOL` are shown in fig 9 and 10.
```
        CHARACTER*4 CHNAMS(5)
        INTEGER LNUMBS(5)
        DATA CHNAMS/'OPAL','BRL-','EB ','EBB ','EBP '/
        DATA LNUMBS/   1 ,   1 ,   1 ,   1 , 20 /
        .
        .
        .
        NRS=0
        CALL GDRVOL(5,CHNAMS,LNUMBS,NRS,80.,135.,0.,13.,10.,0.03,0.03)
        CALL GDAXIS(0.,0.,0.,200.)
C   CALL GDXYZ(0)
```

Figure 9: Example of use of `GDRVOL` in the MAster Reference System

```
      CHARACTER*4 CHNAMS(5)
      INTEGER LNUMBS(5)
      DATA CHNAMS/'OPAL','BRL-','EB  ','EBB ','EBP '/
      DATA LNUMBS/    1 ,    1 ,    1 ,    1 ,   20 /
      .
      .
      .
      NRS=1
      CALL GDRVOL(5,CHNAMS,LNUMBS,NRS,55.,135.,0.,5.,5.,0.035,0.035)
      CALL GDAXIS(0.,0.,0.,200.)
C     CALL GDXYZ(0)
```

Figure 10: Example of use of `GDRVOL` in the Daughter Reference System

Draw a volume cut view

```
CALL GDRAWX   (CHNAME,CUTTHE,CUTPHI,CUTVAL,THETA,PHI,UO,VO,SU,SV)
```

CHNAME   (CHARECTER*4) name of volume;
CUTTHE   (REAL) θ angle of the line normal to the cut plane;
CUTPHI   (REAL) ϕ angle of the line normal to the cut plane;
TETHA   (REAL) viewing angle θ;
PHI   (REAL) viewing angle ϕ;
UO   (REAL) u coordinate on the screen of the volume origin;
VO   (REAL) v coordinate on the screen of the volume origin;
SU   (REAL) scale factor for u coordinates;
SV   (REAL) scale factor for v coordinates.

Draws a *cut view* of the volume `CHNAME` with all its *visible* descendants, i.e. draws their intersection with the cut plane normal to the axis given by the angles `CUTTHE, CUTPHI` at the distance `CUTVAL` from the origin. The view point is defined by the angles `THETA, PHI.UO, VO, SU, SV` have the same meaning as in `GDRAW`. These *view parameters*, as well as zoom parameters set by `GDZOOM` are copied in `/GCDRAW/`.

Attributes like colour, surface fill, line width, line style, visibility, etc. can be set by the `GSATT` routine for `CHNAME` and its descendants [GEOM500].

```
CALL GDRAWC   (CHNAME,IAX,CUTVAL,UO,VO,SU,SV)
```

CHNAME   (CHARECTER*4) name of volume;
IAX   (INTEGER) axis of the cut (1=X, 2=Y, 3=Z);
UO   (REAL) u coordinate on the screen of the volume origin;
VO   (REAL) v coordinate on the screen of the volume origin;
SU   (REAL) scale factor for u coordinates;
SV   (REAL) scale factor for v coordinates.

This routine is a special case of the previous `GDRAWX`. Here the cut plane is normal to one of the main axes (`IAX`) and placed at a distance `CUTVAL` from the origin. The view-point is along the same axis.

Fig. 11 gives an example of utilisation of `GDAXIS`, `GDRAW` and `GDRAWX`. Fig. 12 gives an example of use of `GDRAWC`.
```
CALL GDOPT('HIDE','ON')
CALL GSATT('NBOX','COLO',2.)
CALL GSATT('NTUB','COLO',4.)
CALL GDRAW('NBOX',50.,150.,0.,10.,10.,0.01,0.01)
CALL GDRAW('NTUB',50.,150.,0.,10.,10.,0.01,0.01)
CALL GDOPT('HIDE','OFF')
CALL GSATT('*','COLO',1.)
CALL GDRAWX('NBOX',30.,40.,0.,50.,150.,10.,10.,0.01,0.01)
CALL GDAXIS(0.,0.,0.,200.)
```

Figure 11: Example of utilisation of GDAXIS, GDRAW and GDRAWX
```
CALL GDRAWC('OPAL',2,0.,10.,10.,0.01,0.01)
```

Figure 12: Example of utilisation of GDRAWC

Draw Particle Trajectories

1   Visualisation of particle trajectories

The tracks generated by the tracking package, and optionally stored in the data structure `JXYZ`, can be displayed by the routine `GDXYZ` (corresponding to the interactive command `DXYZ`).

The names of the particles and or the track numbers can be added by the routine `GDPART` (corresponding to the interactive command `DPART`).

A special routine has been provided to visualise the tracks during the transport process (`GDCXYZ`), that could be called for instance by `GUSTEP`. That routine shows the tracks while they are transported by the tracking package of `GEANT`, providing a useful interactive debugging tool.

   CALL **GDXYZ** (ITRA)

Draws track number `ITRA` for which space points have been stored in bank `JXYZ` via calls to the routine `GSXYZ`. The view parameters are taken from `/GCDRAW/`.

`ITRA` (`INTEGER`) track number (if 0 all tracks are taken)

The colour and line style corresponds to the track type :

(blue)	dotted line for gammas	. . . .
(red)	solid line for charged particles (except muons)	—————————
(black)	blank/dotted line for neutral hadrons or neutrinos	. . . .
(green)	dashed line for muons	- - - - - - - - - -
(yellow)	dotted line for Čerenkov photons	. . . .

   CALL **GDPART** (ITRA,ISEL,SIZE)

Draws the particle names and/or the track numbers of track `ITRA`, supposing that its space points had been stored in the bank `JXYZ` via the routine `GSXYZ`. At present only primary tracks are displayed by `GDPART` and their name or number is written at the end the track trajectory. The view parameters are taken from `/GCDRAW/`.

`ITRA`   (`INTEGER`) Track number (if 0 all tracks are taken)
`ISEL`   (`INTEGER`)
       `ISEL=x1` draws the track number,
       `ISEL=1x` draws the particle name,
       `ISEL=11` draws both.
`SIZE`   (`REAL`) Character size in cm.

   CALL **GDCXYZ**

If `GDCXYZ` is called at tracking time (for instance by `GUSTEP`), it draws the tracks while tracking is performed, at the same time as they are generated by the tracking package of `GEANT`. This is a very useful interactive debugging tool. The line style is the same as for `GDXYZ`. The view parameters are taken from `/GCDRAW/`.

Here we give an example of the use of `GDPART`:

```
CALL GSATT('HB','FILL',3)
CALL GSATT('HE','FILL',1)
- - - - -
- - - - -

CALL GDRAWC('OPAL',2,5.,10.,10.,0.013,0.013)
CALL GDXYZ(0)
CALL GDPART(0,11,0.25)
```

Drawing Track Hits in Sensitive Detectors

The hits generated by the tracking package and stored in the data structure `JHITS` can be displayed by the following routines:

1. draw one hit (`GDAHIT`); called by the user;

2. draw all the hits of trajectory type sets/ detectors (`GDHITS`);

3. draw all the hits of calorimeter type sets/ detectors (`GDCHIT`).

Different symbols for each subdetector can be used, chosen among hardware characters (dots), software crosses, or from the `HPLOT` table of software characters. The size of the software characters and crosses is given as an argument to `GDAHIT` and `GDHITS`, while it is computed as a function of the hits value in `GDCHIT`. The option `H` of the interactive `MOVE` command gives the possibility to rotate, zoom and translate in real time the hits stored for one event. This allow a 3D display of the event where it is possible to pick one hit with the mouse and have the hit values printed. The interactive command `LENS` allows a detailed visual scanning of the hits displayed (see the interactive section).

    CALL **GDHITS**   (CHUSET,CHUDET,ITRA,ISYMB,SSYMB)

Draws the hit points as stored by `GSAHIT`, which were generated by track `ITRA` in detector `CHUDET` of set `CHUSET`, with the currently selected view parameters in `/GCDRAW/`. The character plotted at each point may be chosen via `ISYMB`:

-1	(small) hardware points	(fast)
0	software crosses	(default)
840/850	empty/full circles	(slow)
841/851	empty/full squares	(slow)
842/852	empty/full triangles (up)	(slow)
843/853	empty diamond/full triangle (down)	(slow)
844/854	empty/full stars	(slow)

More information on the meaning of the `ISIMB` value can be found in the `HPLOT` manual [7]. Any value for `ISYMB` which is not in the above table is equivalent to option 0. Except for `ISYMB = -1`, the size of the character can be chosen by `SSYMB`. On the 2D projection on the screen one can distinguish which set/detector a given track passes, by drawing different symbols for the hits in different sets/detectors. The size of these symbols may then be chosen to suit the scale of the total picture (detectors and tracks).

Note: It is obligatory for the use of this routine that the spatial `MARS` (MAster Reference System) current coordinates of the hits are stored as the first 3 elements of the hit [`HITS200`].

`CHUSET` (`CHARACTER*4`) user set identifier (if '*' all sets are taken)
`CHUDET` (`CHARACTER*4`) user detector identifier (if '*' all detectors are taken)
`ITRA`   (`INTEGER`) number of selected track (if 0 all tracks are taken)
`ISYMB`   (`INTEGER`) character selection number (see table above)
`SSYMB`   (`REAL`) size of characters in cm (if 0, a default of 0.1 is taken)

    CALL **GDCHIT**   (CHUSET,CHUDET,ITRA,ISYMB,SIZMAX,IHIT,HITMIN,HITMAX)

Draws the hit points as stored by `GSCHIT`, which were generated by track `ITRA` in detector `CHUDET` of set `CHUSET`, with the currently selected view parameters in `/GCDRAW/`. Except for `ISYMB = -1` the size of the character is chosen as a function of `HITS(IHIT)`:
```
CALL GDRAW('CAVE',40.,40.,0.,10.,10.,.04,.04)
CALL IGSET('TXCI',2.)
CALL GDHITS('DRFT','FSP ',0,850,.3)
CALL IGSET('TXCI',3.)
CALL GDHITS('DRFT','RSP1',0,851,.3)
CALL IGSET('TXCI',4.)
CALL GDHITS('DRFT','RSP2',0,852,.3)
CALL IGSET('TXCI',5.)
CALL GDHITS('DRFT','RSP3',0,853,.3)
```

Figure 13: example of use of `GDHITS`

$$\text{SIZE} = \text{sizmax} * (\text{hits(ihit)} - \text{hitmin}) / \text{hitmax}$$

Note: It is obligatory for the use of this routine that the spatial `MARS` (MAster Reference System) current coordinates of the hits are stored as the first 3 elements of the hit [`HITS200`].

SIZMAX (`REAL`) maximum character size in cm
IHIT   (`INTEGER`) `HITS(IHIT)` contains the calorimeter hit value. `IHIT>3`, and the first three elements are supposed to contain the space position of the hit
HITMIN (`REAL`) minimum boundary of `HITS(IHIT)`
HITMAX (`REAL`) maximum boundary of `HITS(IHIT)`

> CALL **GDAHIT**   (X,Y,Z,ISYMB,SSYMB)

Draws one hit point at coordinates `X`, `Y`, `Z`. This routine is useful when the user wants only to display but not to store the hits. The first three arguments are the position of the hit in the `MARS`, and the last two arguments have the same meaning as the similar arguments in GDHITS.

X   (`REAL`) x coordinate in `MARS` of the hit point
Y   (`REAL`) y coordinate in `MARS` of the hit point

X   (REAL) z coordinate in MARS of the hit point

An example of use of the hits drawing routines is given in fig 13.

Drawing the geometrical tree

The geometrical tree is a hierarchical representation of the structure of the detector, based on the mother-daughter relationship among the various volumes composing it. The `GDTREE` routine (corresponding to the `DTREE` interactive command) allows the drawing of the logical tree, displaying name, multiplicity and other information about the volumes.

```
        CALL GDTREE  (CHNAME,LEVMAX,ISEL)
```

CHNAME (`CHARACTER*4`) volume name;

LEVMAX (`INTEGER`) depth levels (if 0 all levels are taken) default is 3;

ISEL   (`INTEGER`) used to select options in the picture of the tree:

      `0` only the node name is drawn;

    `xxxx1` multiplicity is added:

        • each node that has been positioned several times (by `GSPOS` or `GSPOSP`) has a multiplicity number preceded by the symbol '*';

        • each node that has been obtained by division mechanism (by `GSDVN`, `GSDVT`, etc.) has a multiplicity number preceded by the symbol #;

    `xxx1x` `ONLY` information is added. volumes that are `MANY` will be drawn as three square nodes, one overlapping the others but slightly shifted;
        Note: if `CHNAME` itself is `MANY` it will not be recognised as such, because this information is stored in its mother which is unknown;

    `xx1xx` `DET` information is added; if a volumes is a detector it is drawn as a square node with another one slightly larger around it;

    `x1xxx` `SEEN` information is added; if a volume is not seen (either because of its `SEEN` attribute or because of its ancestors `SEEN` attributes affecting the whole tree path) its square node is drawn by using dashed lines;

    `1xxxx` a little picture of the volume is added above each node.

`GDTREE` draws the tree of the volume data structure starting from the volume `CHNAME`, for `LEVMAX` depth levels; a continuation link line is drawn for those elements at the last level on the picture but having descendants. An example of use of `GDTREE` can be found in Fig. 14. For every node, as many red arrows as the number of existing levels below it are plotted on the link; vice versa, as many green arrows as the number of existing levels before it are also plotted. When running `GEANT` interactively, if the `ISEL` argument is not specified, control is given to the mouse after issuing the `DTREE` command. This allows the display of various volume parameters and the navigation of the geometrical tree by clicking the mouse buttons. The size of the picture and the dimensions of each element and arrows are computed automatically.

Interactive use

In an interactive session, control can be given to the mouse:

  • clicking on the left button when the cursor is inside a volume *pave* will generate a `DSPEC` command for that volume;

  • clicking the same button when the cursor is on a red arrow will perform a `DTREE` for the volume preceding the arrow, displaying a number of levels which depends on the which arrow has been selected;
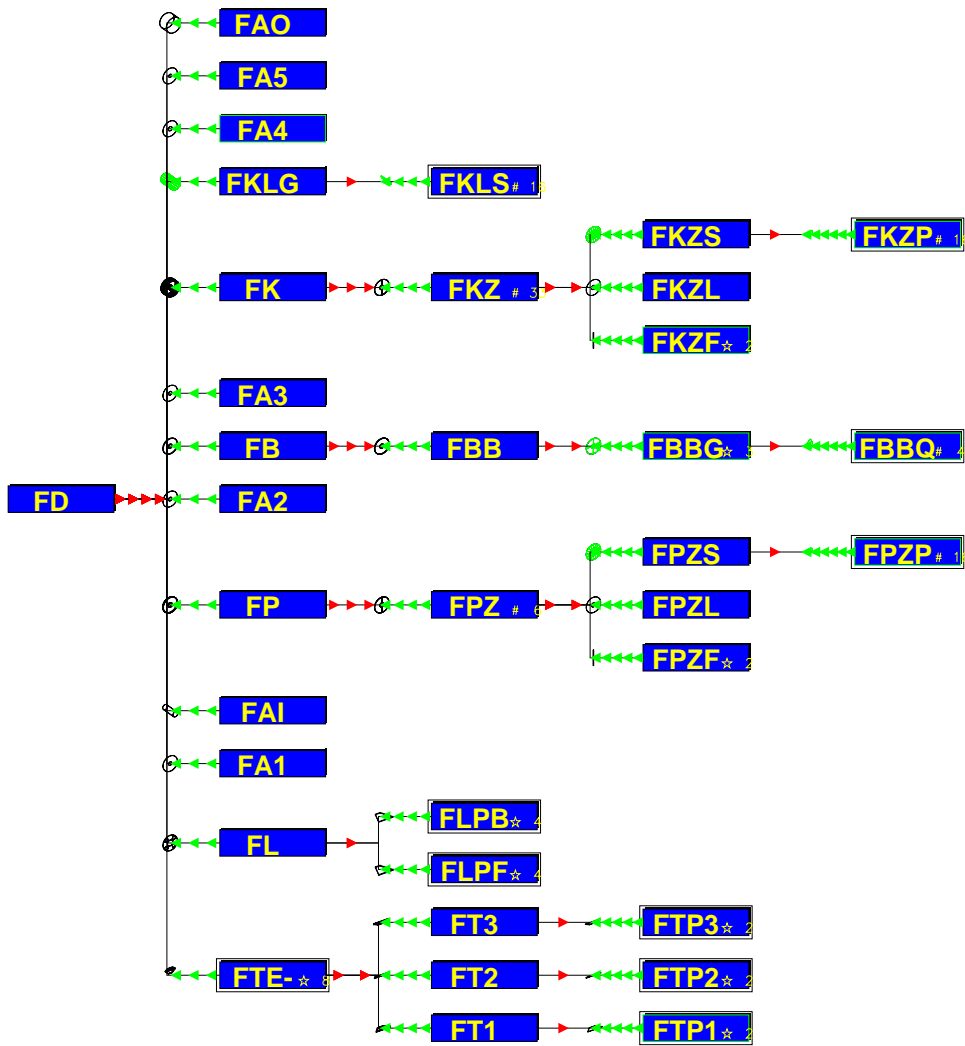

```
CALL GDTREE('FD  ',5,11111)
```

Figure 14: Example of geometrical tree structure

- selecting in the same way the ith green arrow preceding a given volume will perform a `DTREE` for its mother-volume staying *i* levels before;

- clicking the right button of the mouse will return the control to the command mode.

When running with the X-windows software, the drawing of the specification (`DSPEC`) appears in a different window to speed up the scanning of the tree. Iterating this procedure it is possible to analyse very easily and quickly any kind of geometry. This drawing tree capability can be very useful when tuning the detector geometry. See the interactive section [XINT] for examples.

Drawing volume specifications

The geometrical parameters of the volumes can be displayed via the `GDSPEC` routine (corresponding to the `DSPEC` interactive command). This facility provides a detailed picture of a particular piece of the detector. The set of geometrical specifications of all the descendants of a given node on the tree, can be obtained each on a separate picture with the routine `GDFSPC` (`DFSPC` interactive command).

```
CALL  GDSPEC   (CHNAME)
```

`CHNAME`   (`CHARACTER*4`) volume name;

Draws a picture showing all specifications for a given volume. An example of use of `GDSPEC` can be found in Fig. 15.
Figure 15: Example of use of `GDSPEC`

The following information on the volume are presented in a single frame:

- the volume daughters (one level down in the geometrical tree);

- a space view of the volume (with θ=45 and ϕ=135);

- a front view cut;

- a side view cut;

- the axes of the local coordinate system;

- a human figure;

- the scale;

- the shape type;

- all the numerical parameters that define the volume.

In drawing the volumes GDSPEC turns on the sets visibility ('SEEN') attribute for the volume CHNAME itself and its direct descendents. The setting of drawing options (HIDE, CVOL, FILL . . .) will be respected, allowing to customise the drawing. An example is shown in Fig. 16.
Figure 16: Example of use of GDSPEC

```
CALL GDFSPC  (CHNAME,ISORT,INTER)
```

Draws on separate pictures the full set of GDSPEC for the geometrical tree starting from CHNAME, i.e. calls GDSPEC for the volume CHNAME and for all its descendants.

CHNAME   (CHARACTER*4) volume name;

ISORT   (INTEGER) alphabetic sorting flag;

         $= 1$ all the volumes will be drawn in ascending alphabetic order according to their name;

         $\neq 1$ the volumes will be drawn in the order in which they have been created;

INTER   (INTEGER) interactive/batch version flag;

         $= 1$ the routine will prompt the user at each plot before doing a clear screen;

         $\neq 0$ the routine will clear automatically the screen before starting a new frame.

Note: INTER should be set to 1 when using the interactive version of GEANT and to any other value when using a batch version.

Handling View banks

1   The view banks

The basic detector drawing routines (`GDRAW, GDRAWC, GDRAWX`) scan the data structure `JVOLUM` repeatedly to extract position and dimension information on the volumes. This can be a rather lengthy process even on fast computer. Hidden line removal drawing requires an auxiliary data structure and the relative visibility of all the volumes has to be analysed. With complicated detectors the time spent in this process can be substantial, depending on the drawing options chosen and on the speed of the machine on which the program is run. In order to alleviate this problem the graphic *banks* and the associated routines have been developed.

The interpretation of the structure (for instance scanning of the volumes' data structure to convert the 3D geometry structure into a set of 2D lines, visibility analysis, surface creation or light processing) is thus separate from the drawing itself. In this way, the interpretation is performed only once and all the 2D information is stored in view banks (data structure `JDRAW [DRAW399]`). These views can then be displayed quickly, having only to draw the 2D vectors or the fill areas previously stored.

For a detector with more than 100 different volumes, for example, this costs only a few thousand words of memory for each drawing stored.

If the drawing routines are called while a view bank, identified by a positive integer, is open (`GDOPEN`) only interpretation will be made, no output will be generated until the bank is closed (`GDCLOS`). When a view bank has been closed it cannot be modified, but it can be displayed as many times as wanted (`GDSHOW`) or deleted (`GDELET`).

Once a drawing (detectors, tracks or hits) is in a view bank, it is possible to scan it in detail via the `LENS` or `ZOOM` interactive commands (only available with `X11`). For more information see the `[XINT]` section.

```
   CALL GDOPEN  (IVIEW)
```

IVIEW   (`INTEGER`) view bank number (`IVIEW>0`).

Opens a *view bank*, used to store 2D graphics information coming from the interpretation of 3D structures (but also 2D annotation). All subsequent calls to the drawing routines will fill the view bank `IVIEW`, without generating any output.

```
   CALL GDCLOS
```

Closes the current opened view bank. Once a view bank has been closed no more drawing can be added to it. A call to `GDCLOS` also restores the screen.
```
   CALL GDSHOW  (IVIEW)
```

IVIEW   (`INTEGER`) view bank number (`IVIEW>0`).

Displays view bank `IVIEW`. `GDSHOW` can be called either before or after a view bank has been closed. If a view bank is currently open, the content of bank `IVIEW` will be added to it.

```
   CALL GDELET  (IVIEW)
```

IVIEW   (`INTEGER`) view bank number (`IVIEW>0`).

```
CALL GDOPEN(3)
CALL GDRAWC('ALEF',2,5.,10.,10.,0.013,0.013)
CALL GDCLOS
CALL GDSHOW(3)
.
.
CALL GDXYZ(0)
```

Figure 17: Example of use of view banks

Deletes a view bank from memory. If called before a bank has been closed, `GDELET` will also restore the screen mode.

Note: the `JDRAW` data structure has a top level bank which contains one word for each view bank in `Q(JDRAW+IVIEW)`. This word is a key which determines the status of the bank. If this key is 3, the bank itself is protected against deletion, and it cannot be deleted by `GDELET`. An example of use of view banks is shown in Fig. 17.

The data structure `JDRAW`

This data structure contains the so-called *view banks*. The layout of the data structure can be found in Fig. 18. The meaning of the variables is the following:

NKVIEW	number of views stored in the structure;
IVIEW	current view selected;
IGU	current graphic unit pointer;
MAXGU	number of units in graphic unit bank;
MORGU	number of words to push the graphic unit bank;
IGS	current graphic segment pointer;
MAXGS	number of segments in graphic segment bank;
MORGS	number of words to push the graphic segment bank;
ITU	current text unit pointer;
MAXTU	number of units in text unit bank;
MORTU	number of words to push the text unit bank;
ITS	current text segment pointer;
MAXTS	number of segments in text segment bank;
MORTS	number of words to push in text segment bank
LENGU	array of lengths for each graphic unit and of line attributes (LINATT);
ADDGU	array of addresses for each graphic unit;
ADDTU	array of addresses for each text unit;
X	array of u coordinates of graphic segments;
Y	array v coordinates of graphic segments;
ICUT	cut axis (1, 2, 3 or 0 if no cut) of the view;
LINWID	text line width and text attributes (ITXATT);

GTHETA, GPHI, GPSI, GUO, GVO, GSCU, GSCV, are the viewing parameters stored in /GCDRAW/.

UO, VO, SIZE, ANGLE, IOPT, ITEXT have the same meaning of those given as arguments to GDRAWT (or HPLSOF [7]).

A control word is stored in Q(JDRAW+IVIEW), with the following meaning:

|	
1	empty bank (created by internal routines to avoid gaps) or for deleted banks;
2	bank created by the user;
3	protected bank reserved for internal use: it cannot be deleted by the user.

Utility routines of the drawing package

CALL **GDOPT**   (CHOPT,CHVAL)

CHOPT   (CHARACTER*4) option to be set;
CHVAL   (CHARACTER*4) value to be assigned to the option.

Drawing options can be set via the routine GDOPT (corresponding to the DOPT interactive command). The possible value of CHOPT and of CHVAL are the following:

PROJ   selects the type of projection, it can have the following values:

        PARA   orthographic parallel projection (the default);

        PERS   perspective projection.

THRZ   acronym for Tracks and Hits in a Radius versus Z projection, where R is the *vertical* axis of the drawing and Z the horizontal one. If a *cut view* has been drawn with the following parameters:

        X-Z cut   CUTTHE=90 and CUTPHI=90 in GDRAWX or icut=2 in GDRAWC;

        Y-Z cut   CUTTHE=90 and CUTPHI=180 in GDRAWX or icut=1 in GDRAWC.

        the different values of the option THRZ have the following effect on the drawing of hits and tracks:

        360   hits and tracks will be rotated around Z onto the Z-R, R>0 half plane;

        180   (equivalent to ON) hits and tracks will be rotated around Z onto the Z-R plane by the smaller ϕ angle, so to conserve the sign of their R-ordinate (where R is either X or Y;

        OFF   (the default) tracks and hits will be projected from their position in space onto the plane R-Z.

        Note: when the THRZ option is set to ON or 180, particles originating in one half space and crossing the horizontal axis will be reflected back into the original half space. If the option 360 can be chosen, all tracks and hits are on the top (positive) half space.

TRAK   selects the way tracks are drawn. Possible values:

        LINE   (the default) the lines joining track points are drawn by GDXYZ;

        POIN   only the track points are drawn.

HIDE   selects the hidden line removal technique for the drawings. Possible values are:

        OFF   (the default) hidden lines are not removed from the drawing: the drawing is usually rather fast, but the result can be quite messy if a large number of volumes is visible;

        ON   hidden lines are not drawn: if this value is selected, the detector can be exploded (interactive command BOMB), cut with different shapes (interactive command menu CVOL), and some parts can be shifted from their original position (interactive command SHIFT). Drawing with hidden line removal can be demanding in terms of CPU time and memory. At the end of each drawing the program displays the memory used and the statistics on the volume visibility. When the drawing requires more memory than available, the program will evaluate and display the number of missing words, so that the user can increase accordingly the size of the ZEBRA store in the common /GCBANK/.

SHAD   when HIDE is ON, selects the shading and filling option for the detector's surfaces that are drawn:

        OFF   (the default) no shading of the surfaces will be performed;

ON	the volume surfaces will be filled according to the value of their `FILL` and `LWID` attribute, set via `GSATT`:

`FILL=1`	the surfaces are filled with the current colour assigned to the volume via `GSATT`, 166 different colours are available;
`FILL>1`	the surfaces are filled with a shade of the basic colour assigned to the volume according to their angle with respect to the line of illumination, the resolution increases with the value of `FILL` ($1<$ `FILL` ≤ 7);
`LWID>0`	just as the number of scan-lines used to fill a surface depends on the value of `FILL`, their width depends on the value of `LWID`: increasing the value of `LWID` will result in thicker lines.

EDGE	control drawing of the volume edges in `HIDE=ON`, `FILL=ON` mode:

ON	the edges of the faces are not drawn, so that they will be visible only as intersections of filled faces with different luminosity;
OFF	the edges of the faces are drawn. For the volumes which are not filled, the normal edges will be drawn irrespective of the value of this option.

CALL **GDZOOM** (ZFU,ZFV,UZO,VZO,UO,VO)

ZFU	(`REAL`) zoom factor for `U` coordinate;
ZFV	(`REAL`) zoom factor for `V` coordinate;
UZO	(`REAL`) `U` coordinate of centre of zoom;
VZO	(`REAL`) `V` coordinate of centre of zoom;
UO	(`REAL`) `U` coordinate of centre of zoom in the resulting picture;
VO	(`REAL`) `V` coordinate of centre of zoom in the resulting picture.

This routine sets the zoom parameters (part of the viewing parameters in common `/GCDRAW/`) that define how objects will be displayed by the subsequent drawing operations. The zoom is computed around `UZO`, `VZO` (user coordinates). This point will be moved to `UO`, `VO` in the resulting picture. `ZFU`, `ZFV` are the zoom factors (positive). If `ZFU` or `ZFV` are zero, the zoom parameters are reset, and the original viewing is restored.

CALL **GDAXIS** (XO,YO,ZO,AXSIZ)

XO	(`REAL`) X coordinate of origin;
YO	(`REAL`) Y coordinate of origin;
ZO	(`REAL`) Z coordinate of origin;
AXSIZ	(`REAL`) axis size in centimeters.

Draws the axes of the `MA`ster Reference System, corresponding to the current viewing parameters. All the arguments refer to the `MARS`.

CALL **GDSCAL** (UO,VO)

UO	(`REAL`) `U` coordinate of the centre of the scale;
VO	(`REAL`) `V` coordinate of the centre of the scale.

Draws a scale corresponding to the current viewing parameters. Seven kinds of units are available, from 1 micron to 100 cm. The best unit is automatically selected.

CALL **GDMAN** (UO,VO)

CALL **GWOMA1** (UO,VO)

CALL **GDWMN2** (UO,VO)

CALL **GDWMN3** (UO,VO)

UO	(REAL) U coordinate of the centre of the figure;
VO	(REAL) V coordinate of the centre of the figure.

Draws the profile of a man, or three different female figures in 2D user coordinates, with the current scale factors. The figure is approximately 160 cm high.

```
CALL GDRAWT   (U,V,CHTEXT,SIZE,ANGLE,LWIDTH,IOPT)
```

U	(REAL) U position of text string;
V	(REAL) V position of text string;
CHTEXT	(CHARACTER*(*)) text string;
SIZE	(REAL) character size (cm);
ANGLE	(REAL) rotation angle (degrees);
LWIRTH	(INTEGER) line width (1,2,3,4,5);
IOPT	(INTEGER) centering option for the text:

      -1   left adjusted;

       0   centered;

       1   right adjusted.

Draws text with software characters. It has the same arguments of the HPLOT [7] routine HPLSOF (a call to HPLSOF is actually performed).

```
CALL GDRAWV   (U,V,NP)
```

U	(REAL) array of U coordinates;
DT	(REAL) array of V coordinates;
NP	(INTEGER) number of points.

Draws 2D polylines in user coordinates. The routine GDFR3D can be called to transform 3D points in 2D user coordinates.

```
CALL GDHEAD   (ISEL,CHNAME,CHRSIZ)
```

ISEL	(INTEGER) option to be selected for the title name (decimal integer):

        0   only the header lines;

    xxxxx1   add the text CHNAME centered on top of header;

    xxxx1x   add global detector name (first volume) on left;

    xxx1xx   add date on right;

    xx1xxx   select thick characters for text in top of head (i.e. with larger line width);

    x1xxxx   add the text EVENT NR x on top of header;

    1xxxxx   add the text RUN NR x on top of header.

    Note: ISEL=x1xxx1 or ISEL=1xxxx1 are illegal choices, i.e. they generate overwritten text.

CHNAME	(CHARACTER*4) title string;
CHRSIZ	(REAL) character size (cm) of text CHNAME.

This routine draws a frame header.

```
CALL GDCOL   (ICOL)
```

This routine has been kept for backward compatibility. The appropriate HIGZ routines should be called instead.

ICOL	(INTEGER) colour code (1,2,...,8), it can be positive, negative, or zero:

    >0   to set the colour permanently;

    <0   to set the colour temporarily;

$=0$ to restore the permanent colour value.

This routine sets the colour code. For example we can set `ICOL=-1` to start with colour 1, then change to `ICOL=3` to set colour 3, and at the end restore the original colour by setting `ICOL=0` that takes colour 1 again.

     CALL **GDLW**   (LW)

This routine has been kept for backward compatibility. The appropriate `HIGZ` routines should be called instead.

LW   (`INTEGER`) line width code (1,2,...,5), it can be positive, negative, or zero:

     >0 to set the line width permanently;

     <0 to set the line width temporarily;

     $=0$ to restore the permanent line width value.

This routine sets the line width. For example we can set `LW=-1` to start with line width 1, then change to `LW=3` to set line width 3, and at the end restore the original line width by setting `LW=0` that takes line width 1 again.

     CALL **GDCURS**   (UO*,VO*,ICHAR*)

UO   (`REAL`) U coordinate of the graphics cursor;

VO   (`REAL`) V coordinate of the graphics cursor;

ICHAR   (`INTEGER`) `ASCII` value of the key pressed.

A graphics input is provided by this routine to fetch the 2D user coordinates of the graphics cursor on the screen. Interactive commands to zoom, measure, or pick tracks or hits make use of this routine. When the routine is called in the interactive version of `GEANT`, the present position of the graphics cursor on the screen becomes visible and it can be moved with the mouse. The user then positions the cursor and presses the left button. The routine returns then in UO, VO the user coordinates of the graphics cursor. On terminals which do not have the mouse, the graphic cursor is moved with the arrows, and the point is acquired when any key, except *carriage return*, is pressed. In this case the routine returns in ICHAR the `ASCII` value of the key pressed. If the user types the carriage return, the previous value is retained.

     CALL **GDFR3D**   (X,NPOINT,U*,V*)

X   (`REAL`) array X(3,NPOINT) of space points;

NPOINT   (`INTEGER`) number of points:

     >0 X is in the current DRS;

     <0 X is in MARS;

U   (`REAL`) array of NPOINT U coordinates;

V   (`REAL`) array of NPOINT V coordinates.

Converts from 3D space coordinates (either in MAster or Daughter Reference System) to the corresponding 2D user coordinates.

This routine maps a space point (X, Y, Z in a right-handed reference system) onto a plane perpendicular to the observer's line of sight, defined by the spherical angles θ, ϕ:

θ the angle between the line of sight and the Z axis ($0 \leq \theta \leq 180$);

ϕ the angle between the X axis and the projection onto the X-Y plane of the line of sight ($0 \leq \phi \leq 360$).

The plane onto which the point is mapped is actually the X-Y plane of the Projection Reference System, and the observer's line of sight is the Z axis of PRS. The vertical axis on this plane (Y axis on PRS) is obtained by intersecting this plane with the one of MARS or DRS containing the line of sight and the Y axis.

     CALL **GD3D3D**   (XIN,NPOINT,XOUT*)

XIN   (REAL) array XIN(3,NPOINT) of input points in MARS;

NPOINT   (INTEGER) number of points;

XOUT   (REAL) array XOUT(3,NPOINT) of output points in PRS.

Converts from 3D space coordinates in MARS to 3D coordinates in Projection Reference System (whose Z axis is along the line of sight given by θ and ϕ angles).

The geometry package

The geometry package has two main functions:

1. define, during the initialisation of the program, the geometry in which the particles will be tracked;

2. communicate, during the event processing phase, to the tracking routines the information for the transport of the particles in the geometry which has been defined.

The present section reviews the concepts of the geometry package and explains how the geometrical information should be provided by the user. It is important to point out that, once the geometry has been defined, the tracking of particles through the different volumes proceeds without any intervention from the user [TRAK].

The connection between the geometry and tracking packages is established by the subroutines GMEDIA/GTMEDI, GTNEXT/GNEXT and GINVOL which answer respectively the questions:

- In which volume is a given point ?

- What is the distance to the nearest volume along the trajectory of the particle ?

- What is the distance to the nearest volume ?

- Is a given point still in the current volume ?

The routines GTMEDI, GTNEXT are used in a dynamic context, at tracking time, when the knowledge of the track direction can be used to save time.

1 The volume definition

Experimental setups, as complex as the LEP[1] detectors, can be described rather accurately through the definition of a set of *volumes*. Each *volume* is given a *name* and is characterised by:

- a *shape* identifier, specifying one of the basic geometrical shapes available [GEOM050];

- the *shape* parameters, giving the dimensions of the volume;

- a local reference system, with origin and axes defined for the each shape;

- the physical properties, given by a set of constants describing the homogeneous *material* which fills the volume ([CONS]);

- additional properties, known as *tracking medium* parameters, which depend on the characteristics of the volume itself (the material identifier is one of the constants) and on its geometrical and physical environment (properties of the neighbouring volumes, magnetic field, etc.) [CONS, TRAK];

- a set of attributes, in connection with the drawing package and the detector response package [DRAW, HITS].

Until it is *positioned* in a given reference frame, a volume is an entity which has no spatial relation with the other volumes. By convention, a unique initial volume has to be defined first which will contain all the other volumes. The reference frame intrinsic to this volume is considered to be the master reference frame.

There are sixteen basic shapes in GEANT, which are described in [GEOM050].

---

[1] The Large Electron Positron collider in operation at CERN.

2 Volumes with contents

A *volume* can be declared to have contents and as such it becomes a *mother* volume. The contents are *either* predefined volumes which are explicitly positioned inside the mother, *or* new volumes which are implicitly defined by a division mechanism applied to the mother. Positioning a volume with given shape and dimensions inside a mother volume is obtained by specifying its translation and rotation with respect to the mother reference frame. The user should make sure that no volume extends beyond the boundaries of its mother.

When a volume is positioned, the user gives it a *number*. Multiple copies of the same volume can be positioned inside the same or different mothers as long as their copy numbers differ. The contents of the positioned volume are reproduced in all copies.

Mother volumes can be divided by planes along the three axes (x, y, z), radially along R_{xy}, or along the spherical coordinates of a polar system: R, θ and ϕ. The axis along which it is possible to perform a division depend on the shape to be divided. The general rule is that the result of the division be still a `GEANT` shape.

A volume can be partially or totally divided. The division process generates a number of *cells*, which are considered as new volumes. The cell dimensions are computed according to the number of divisions or the step size. A cell, as any other volume, can again be divided, or have other volumes positioned into it. Any operation of positioning or division performed on one cell is repeated to all the cells resulting from the division. A volume can be *either* divided *or* have contents, but not the two things together.

These operations define a physical tree with several levels. The material and properties of the contents replace the ones of the mother within the space region they occupy. A `volume` is therefore defined not only by its intrinsic characteristics but also by those of its *descendants*, namely its contents (by division or positioning), the contents of its contents, etc.

3 Overlapping volumes, see also [`GEOM020`]

The user may define volumes which have no relation with the real objects. It is sometimes convenient to make use of such volumes, to artificially delimit regions with simple shapes. Doing this, it may happen that volumes partially overlap each other. (A volume positioned inside a mother is obviously not regarded as overlapping the mother).

It is possible in `GEANT` to handle partially overlapping volumes, but there are some implications that the user should be aware of. A flag `'ONLY'`/`'MANY'` is assigned to each copy of a given volume at the moment this is positioned. The `'MANY'` option indicates that a point found in this volume could also be in other volumes which are not its direct descendants. If one of the overlapping volumes where the point is found is declared as `'ONLY'`, the geometry subroutines will give priority to this volume, and the search stops. If a point is inside several `'MANY'` volumes and outside all `'ONLY'` ones, priority will be given to the volume found at the deepest level, or to the first found, if there are many valid `'MANY'` candidates at the same level. In order to avoid ambiguities, two overlapping `'MANY'` volumes should in general have the same tracking medium.

4 The physical tree

An example of a 4 level physical tree with embedded volumes and the corresponding geometrical configuration are shown in fig 19.

where A and B are `BOX`es, C a `TRAP`ezoid, and D and E `TUBE`s (see [`GEOM050`] for more detail). Notice that the same physical configuration could be described as well though a 3 level tree if D were defined as a *hollow* `TUBE`, with inner radius non-zero and E directly positioned into B. The package accepts a maximum of 15 levels, which should be enough to represent the fine details of a complex structure.

5 The data structures `JVOLUM` and `JGPAR` and the common `/GCVOLU/`

In practice, the physical tree is not represented as such in the data part of the program. Instead, a logical tree structure is defined, the `JVOLUM` data structure, which describes the arrangement of volumes in a compact and
Figure 19: Example of geometrical tree structure

recurrent way. Each generic volume appears once, and once only, and carries the information relevant to the volume itself and to its contents, if any, by reference to the generic volumes corresponding to those contents. In the situation where division or multiple copies occur, there is no longer a one-to-one correspondence between a volume in the logical tree and a region in space. Information has to be added at tracking time to identify which division cell or which copy was considered at each depth level along the path through the physical tree. This information is stored by the subroutine `GMEDIA/GTMEDI`, for the current point of the current track, in the common `/GCVOLU/`. It includes the current level number `NLEVEL` and, for each level, starting from the first mother volume, the identification of the corresponding volume, e.g.: `NAME`, `NUMBER`, `'ONLY'/'MANY'` flag, translation and rotation with respect to the master reference frame and so on. The number of shape parameters and pointers to the vector describing the actual values of those parameters, for each level, are stored in the data part and in the link part, of the data structure `JGPAR`, respectively.

6 The user tools

The geometry through which the particles are transported is defined by the user via a set of calls to subroutines of the `GEANT` package.

The user can define a volume through a call to the subroutine:

GSVOLU   define (*instantiate*) a volume by giving a `NAME` and the actual parameters to a shape; the position of the volume inside the bank `JVOLUM` is returned. If any of the parameters which express a length is negative, `GEANT` will assign to this parameter at tracking time the maximum value allowed, without protruding out of the mother which contains the particle transported.

A shape can be instantiated into a volume also without actual parameters. These will then be supplied when positioning each copy of the volume via the `GSPOSP` routine (see below). This allows to have many *similar* volumes with the same name and shape, but different actual parameters in each copy.

The user can position a volume through a call to either one of the following subroutines:

GSPOS   position a copy of a volume inside its mother with respect to the mother's reference system. A a point in space, a rotation matrix index, a copy number and the `'ONLY'/'MANY'` flag are supplied;

GSPOSP   position a copy of a volume which has been instantiated without actual parameters inside its mother with respect to the mother reference system. The parameters of the copy being positioned are supplied as well. The volumes will be identified by name and copy number as for multiple copies of the same volume.

The user can divide a volume through a call to either one of the following subroutines:

GSDVN   divide a volume in a given *number* of cells completely filling the mother. In this case the cell tracking medium is assumed to be the same as for the mother. See also GSDVN2.

GSDVT   divide a volume with slices of a given *step*. The cell tracking medium can be different from the one of the mother. See also GSDVT2.

GSDVX   divide a volume starting from a given offset. In addition to STEP and NDIV (with at least one of them positive to be effectively useful), the origin of the first cell, the cell tracking medium and eventually the computed (maximum) number of divisions must be specified.

7   Geometrical information retrieval

The parameters of a volume may depend on the physical tree which leads to this volume. The dimensions of one of the slices of a cone divided along Z depends on which slice we consider. So a volume is completely defined only if we specify the path in the tree. This is composed by the name and copy number of the volumes containing the one we are interested in, from the first mother.

Given this information, the routine GLVOLU is capable to fill the common /GCVOLU/, and the structure JGPAR with the actual parameters of the instance chosen.

Tracking inside volumes and optimisation

The tracking of particles through the geometrical data structure is the key functionality of GEANT. At every particle's step, the program must find the volume where the particle is (GTMEDI) and the next boundary it will cross (GTNEXT). This can take about 60% of the total simulation time (even for detectors described in an optimized way); therefore, a new logic has been introduced to minimize the time spent for the search in the geometrical tree.

1   Virtual divisions

Instead of a linear or binary search (time spent proportional or logarithmic with the number of volumes, respectively), a 'direct access' technique has been developed to make the time basically independent from the number of volumes. Every volume containing other volumes is 'virtually' divided in equal slices at initialization time via the call to GGCLOS (the best axis is computed automatically). For each slice, a data structure is filled with a list of the volumes identifiers intersecting such slice. Slices with identical lists are pointing to the same contents and are collected. At tracking time it is immediate to find in which slice the particle is and only its contents have to be checked. The same is true to find the next boundary to be crossed: only if the intersection point with a content lies outside the current collection of slices, the next one will be checked. The algorithm gives in average about a factor 2 in speed for the overall simulation in the large detectors. It also minimizes the dependency of the performance on the skill and experience of the programmer and allows a fast tracking even in geometrical structures received from CAD systems.

2   Other optimisation tools

The following facilities are kept for backward compatibility reasons. If called by the user, these optimisation tools are called at initialisation time, but not used at tracking time. Instead, the new optimisation using 'virtual divisions' is performed. If the user wants to use the older optimisation tools, he can recompile GEANT 3.21 using the PATCHY flag +OLD.

1. GSORD/GGORD

   From the position of the contents inside a given volume, the subroutine GSORD computes fictitious boundaries along the specified coordinate, simulating a division with irregular step size. A binary search technique is used to identify within which pseudo-cell the current point is. The slow process of computing whether the point is inside or outside the contents is therefore limited to the few (if any) volumes overlapping with that pseudo-cell, as sketched in fig 20.

   The coordinate selected for the pseudo division can be any of X, Y, Z, R_{xy}, R, ϕ or θ;. For a given volume, the call to GSORD has to come after all its first level contents have been positioned.

2. GSNEXT/GSNEAR

   when a particle exits from a daugther of a mother volume, the contents are scanned initially in the order in which they have been positioned, and the user should take care over the best sequence of GSPOS calls. However, when the particle *comes back* inside the mother from any one of the contents, it is usually possible to limit the search to the neighbour contents. The subroutines GSNEXT/GSNEAR permit the user to inject, at initialisation time, for each content in turn, the list of neighbours to search for. GSNEAR is recommended, GSNEXT is kept for backward, compatibility and has a different default option. A proper use of this facility can reduce the search time significantly.
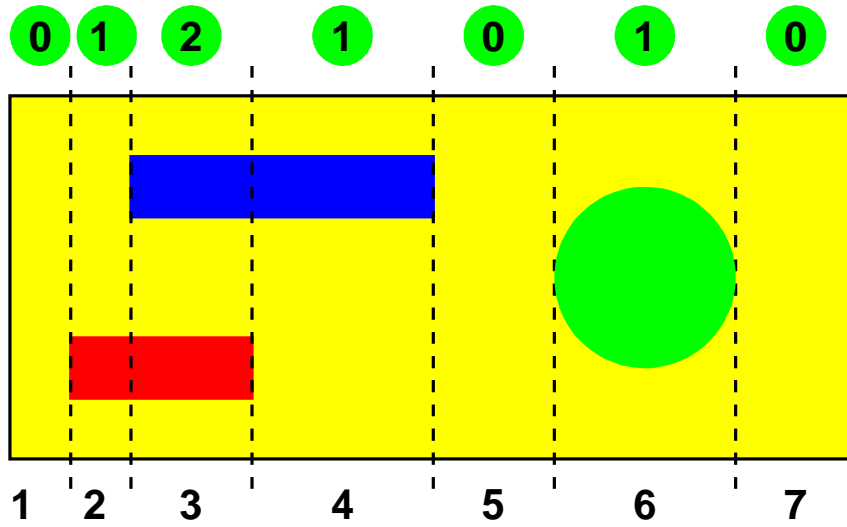

Figure 20: Example of pseudo-cells created by `GSORD`

3. `GSUNEA/GUNEAR`

The volumes to be checked when exiting from one daughter can depend on the direction and position of the exiting particles. To optimise tracking taking into account these dynamic features, the user can code the `GUNEAR` routine, and inform `GEANT` that it has to use it at tracking time by calling the `GSUNEA` routine.

'MANY' Volumes and boolean operations on volumes

The topology of GEANT is given by 16 general shapes which are used to represent solids in the design of detectors. These shapes are bounded by 2-nd order surfaces for reasons of speed at tracking time. New tools have been introduced to extend the power of the GEANT geometry: boolean operations (union, intersection and subtraction) between such shapes are now allowed, so that an infinity of new shapes can be built; divisions along arbitrary axis are now possible, allowing to exploit any simmetry in the design. The tracking is now able to handle overlapping volumes in the most general sense: the concept of MANY volumes has been extended to automatic clipping for protuding objects. Thanks to this MANY technique, any 3D or 2D geometrical pattern can be reduced to a single dimensional structure, basically cancelling the need for GUNEAR at tracking time. Finally, more than one order of magnitude in speed has been gained compared to the old step search algorithm used to track in MANY volumes.

- Topological extensions via boolean operations.

- Divisions along arbitrary axis.

- Reduction of 2D structure to 1D structure.

- Logic and algorithm.

1 Topological extensions via boolean operations

Boolean operations between a given set of shapes allow the creation of an infinite number of shapes. Adding a single new primitive (for ex. a toroid) to the basic set of shapes, all the possible combinations with all the old shapes become moreover possible.

- UNION: the union of two volumes B and C is obtained positioning two overlapping 'MANY' daughters B and C inside the same mother A. To identify the result of the union as a single volume is enough to create a SET associated to the volumes B and C.

- SUBTRACTION: the subtraction of a volume B from a volume C is obtained positioning B as 'ONLY' and C as a 'MANY' overlapping B. The result of the subtraction is automatically what the tracking sees as the C volume, so GSPOS is the only user interface needed. The volume B can have the same material as the mother A or not. The normal positioning technique used for 'ONLYs' is a particular case of boolean subtraction (a volume is contained inside the other).

- INTERSECTION: the intersection of two volumes B and C is obtained positioning a protuding 'MANY' object C in a 'MANY' object B which is normally placed in a 'ONLY' mother A. A and B must have the same material, while C has the material asked for the intersection. The intersection is given by the part of C which is not protuding from B, therefore by what the new tracking sees as the volume C: again the only needed user interface is GSPOS. If not interacting with other daughters of A, B could also be 'ONLY'. Without any ambiguity, even further 'MANY' daughters of A can overlap the protuding part of C outside B, because it is really invisible to the new tracking.

2 Divisions along arbitrary axis

As protuding `MANY` daughters are automatically clipped by their mother, it is possible to divide objects along arbitrary directions. Suppose for example that we want to divide a PCON into planar slices parallel to the plane X + Y = 0; it is enough to position a `MANY` BOX embedding completely the PCON 'inside' the PCON itself; the BOX must be rotated of 45 degrees in X and Y and then divided along one of its natural axis. Another example can be the following: suppose we want to divide 24 times in PHI a PGON with only 6 natural segmentations in PHI; then we have to position a `MANY` TUBE, completely embedding the PGON, 'inside' the PGON itself; again, we can now divide the tube in 24 slices in PHI and the tracking will see only the PGON divided 24 times in PHI.

3 Reduction of 2D structure to 1D structure

Sometimes there are complicated multidimensional geometrical structures (like honeycombs, spaghetti, etc.) which can be reduced to the overlap of several one-dimensional patterns (for which divisions can be used or virtual divisions are particularly efficient). The `MANY` option allows to superimpose such 1D structures to reproduce the multi-dimensional ones in a very effective way, instead of positioning the volumes one by one in the 2D or 3D pattern. A picture will follow which explains this concept better.

4 Logic and algorithm

In `GTMEDI`, all the 'MANY' volumes for which the point is found inside (and not in any of its daughters) is put in a stack saving also its branch of the tree. The point is considered to be in the deepest level 'MANY'. Each time the point is also found in an intermediate 'ONLY' volume the stack is cleared (to insure boolean subtraction). In `GTNEXT`, if stepping inside a 'MANY' volume, not `ONLY` its daughters and its own boundaries are checked, but also the daughters and the boundaries of all the others 'MANY' in the list have to be checked. This is not yet enough: the logic requires that the boundaries of all the possible overlapping volumes are checked, so it is also necessary for each 'MANY' volume of the list to go up to the first 'ONLY' mother in the tree repeating the same procedure. This allows also boolean intersection. Obviously, volumes already checked are not checked again.

The `GEANT` shapes

The `GEANT` geometry package offers sixteen basic shapes with which to describe the setups where particles are transported. In this section we will describe these shapes. For each shape figs (21), (22), (23), (24) show a simple drawing illustrating the meaning of the parameters and the position and orientation of the reference frame proper of that shape. A description of the shapes and of their parameters follows. Angles are always in degrees. With every shape is given the code which is used internally by `GEANT` to identify it.

1 `BOX`   box with faces perpendicular to the axes. It has 3 parameters:

>   1.`DX` half-length of the box along the x-axis;
>
>   2.`DY` half-length of the box along the y-axis;
>
>   3.`DZ` half-length of the box along the z-axis;

2 `TRD1`   trapezoid with the x dimension varying along z. It has 4 parameters:

>   1.`DX1` half-length along x at the z surface positioned at `-DZ`;
>
>   2.`DX2` half-length along x at the z surface positioned at `+DZ`;
>
>   3.`DY` half-length along the y-axis;
>
>   4.`DZ` half-length along the z-axis;

3 `TRD2`   trapezoid with both x and y dimensions varying along z. It has 5 parameters:

>   1.`DX1` half-length along x at the z surface positioned at `-DZ`;
>
>   2.`DX2` half-length along x at the z surface positioned at `+DZ`;
>
>   3.`DY1` half-length along y at the z surface positioned at `-DZ`;
>
>   4.`DY2` half-length along y at the z surface positioned at `+DZ`;
>
>   5.`DZ` half-length along the z-axis;

4 `TRAP`   *general* trapezoid: the faces perpendicular to z are trapezia and their centres are not necessarily on a line parallel to the z axis. This shape has 11 parameters, but only considering that the faces should be planar, only 9 are really independent. A check is performed on the user parameters and a message is printed in case of non-planar faces. Ignoring this warning may cause unpredictable effect at tracking time.

>   1.`DZ` half-length along the z axis;
>
>   2.`THET` polar angle of the line joining the centre of the face at `-DZ` to the centre of the one at `+DZ`;
>
>   3.`PHI` azimuthal angle of the line joining the centre of the face at `-DZ` to the centre of the one at `+DZ`;
>
>   4.`H1` half-length along y of the face at `-DZ`;
>
>   5.`BL1` half-length along x of the side at `-H1` in y of the face at `-DZ` in z;
>
>   6.`TL1` half-length along x of the side at `+H1` in y of the face at `-DZ` in z;
>
>   7.`ALP1` angle with respect to the y axis from the centre of the side at `-H1` in y to the centre of the side at `+H1` in y of the face at `-DZ` in z;
>
>   8.`H2` half-length along y of the face at `+DZ`;

9. `BL2` half-length along x of the side at `-H2` in y of the face at `+DZ` in z;

10. `TL2` half-length along x of the side at `+H2` in y of the face at `+DZ` in z;

11. `ALP2` angle with respect to the y axis from the centre of the side at `-H2` in y to the centre of the side at `+H2` in y of the face at `+DZ` in z;

5 `TUBE`   tube. It has 3 parameters:

1. `RMIN` inside radius;

2. `RMAX` outside radius;

3. `DZ` half length in z;

6 `TUBS` ϕ segment of a tube. It has 5 parameters:

1. `RMIN` inside radius;

2. `RMAX` outside radius;

3. `DZ` half length in z;

4. `PHI1` starting angle of the segment;

5. `PHI2` ending angle of the segment;

`PHI1` should be smaller than `PHI2`. If this is not the case, the system adds 360 degrees to `PHI2`.

7 `CONE`   conical tube. It has 5 parameters:

1. `DZ` half-length in z;

2. `RMN1` inside radius at `-DZ` in z;

3. `RMX1` outside radius at `-DZ` in z;

4. `RMN2` inside radius at `+DZ` in z;

5. `RMX2` outside radius at `+DZ` in z;

8 `CONS` ϕ segment of a conical tube. It has 7 parameters:

1. `DZ` half-length in z;

2. `RMN1` inside radius at `-DZ` in z;

3. `RMX1` outside radius at `-DZ` in z;

4. `RMN2` inside radius at `+DZ` in z;

5. `RMX2` outside radius at `+DZ` in z;

6. `PHI1` starting angle of the segment;

7. `PHI2` ending angle of the segment;

`PHI1` should be smaller than `PHI2`. If this is not the case, the system adds 360 degrees to `PHI2`.

9 `SPHE`   segment of spherical shell. It has 6 parameters:

1. `RMIN` inside radius of the shell;

2. `RMAX` outside radius of the shell;

3. `THE1` starting polar angle of the shell;

4. `THE2` ending polar angle of the shell;

5. `PHI1` starting azimuthal angle of the shell;

6. `PHI2` ending azimuthal angle of the shell;

10 `PARA`   parallelepiped. It has 6 parameters:

1. `DX` half-length in x;

2. `DY` half-length in y;

3. `DZ` half-length in z;

  4.`ALPH` angle formed by the y axis and by the plane joining the centre of the faces parallel to the z-x plane at `-DY` and `+DY`;

  5.`THET` polar angle of the line joining the centres of the faces at `-DZ` and `+DZ` in z;

  6.`PHI` azimuthal angle of the line joining the centres of the faces at `-DZ` and `+DZ` in z;

11 `PGON`   *polygon*. It has at least 10 parameters:

  1.`PHI1` the azimuthal angle ϕ at which the volume *begins* (angles are counted counterclockwise);

  2.`DPHI` *opening* angle of the volume, which extends from `PHI1` to `PHI1+DPHI`;

  3.`NPDV` number of sides of the cross section between the given ϕ limits;

  4.`NZ` number of planes perpendicular to the z axis where the dimension of the section is given – this number should be at least 2 and `NP` triplets of numbers must follow;

  5.`Z` z coordinate of the section;

  6.`RMIN` radius of the circle tangent to the sides of the inner polygon in the cross-section;

  7.`RMAX` radius of the circle tangent to the sides of the outer polygon in the cross-section;

12 `PCON`   *polycone*. It has at least 9 parameters:

  1.`PHI1` the azimuthal angle ϕ at which the volume *begins* (angles are counted counterclockwise);

  2.`DPHI` *opening* angle of the volume, which extends from `PHI1` to `PHI1+DPHI`;

  3.`NZ` number of planes perpendicular to the z axis where the dimension of the section is given – this number should be at least 2 and `NP` triplets of numbers must follow;

  4.`Z` z coordinate of the section;

  5.`RMIN` radius of the inner circle in the cross-section;

  6.`RMAX` radius of the outer circle in the cross-section;

13 `ELTU`   elliptical cross-section tube. It has three parameters:

  1.`P1` semi-axis of the ellipse along x;

  2.`P2` semi-axis of the ellipse along y;

  3.`DZ` half-length in z;

The equation of the surface is $x^2 \mathtt{P1}^{-2} + y^2 \mathtt{P2}^{-2} = 1$.

14 `HYPE`   hyperbolic tube, i.e. the inner and outer surfaces are hyperboloids, as would be formed by a system of cylindrical wires which were then rotated tangentially about their centres. It has 4 parameters:

  1.`RMIN` inner radius at z=0, where tube is narrowest;

  2.`RMAX` outer radius at z=0, where tube is narrowest;

  3.`DZ` half-length in z;

  4.`THET` *stereo angle* of rotation of the two faces;

The hyperbolic surfaces are given by: $r^2 = (z \tan \theta)^2 + r^2_{z=0}$

28 `GTRA`   general twisted trapezoid: the faces perpendicular to z are trapezia and their centres are not necessarily on a line parallel to the z axis as the `TRAP`; additionally, the faces may be *twisted* so that none of their edges are parallel. It is a `TRAP` shape, except that it is *twisted* in the x-y plane as a function of z. The parallel sides perpendicular to the z axis are rotated with respect to the x axis by an angle `TWIST`, which is one of the parameters. The shape is defined by the eight corners and is assumed to be constructed of straight lines joining points on the boundary of the trapezoidal face at z=-DZ to the corresponding points on the face at z=DZ. Divisions are not allowed. It has 12 parameters:

1. DZ half-length along the z axis;

2. THET polar angle of the line joining the centre of the face at -DZ to the centre of the one at +DZ;

3. PHI azimuthal angle of the line joining the centre of the face at -DZ to the centre of the one at +DZ;

4. TWIST *twist* angle of the faces parallel to the x-y plane at $z = \pm DZ$ around an axis parallel to z passing through their centre;

5. H1 half-length along y of the face at -DZ;

6. BL1 half-length along x of the side at -H1 in y of the face at -DZ in z;

7. TL1 half-length along x of the side at +H1 in y of the face at -DZ in z;

8. ALP1 angle with respect to the y axis from the centre of the side at -H1 in y to the centre of the side at +H1 in y of the face at -DZ in z;

9. H2 half-length along y of the face at +DZ;

10. BL2 half-length along x of the side at -H2 in y of the face at +DZ in z;

11. TL2 half-length along x of the side at +H2 in y of the face at +DZ in z;

12. ALP2 angle with respect to the y axis from the centre of the side at -H2 in y to the centre of the side at +H2 in y of the face at +DZ in z;

Note: this shape suffers from the same limitations than the TRAP: the tracking routines assume that the faces are planar, but this constraint is not easily expressed in terms of the 12 parameters. Additionally, no check on the faces is performed in this case. Users should avoid to use this shape as much as possible, and if they have to do so, they should make sure that the faces are really planes. If this is not the case, the result of the transport is unpredictable.

To accelerate the computations necessary for transport, 18 additional parameters are calculated for this shape:

1. DXODZ dx/dz of the line joining the centres of the faces at z=$\pm$DZ;

2. DYODZ dy/dz of the line joining the centres of the faces at z=$\pm$DZ;

3. X01 x at z=0 for line joining the + on parallel side, perpendicular corners at z=$\pm$DZ;

4. Y01 y at z=0 for line joining the + on parallel side, + on perpendicular corners at z=$\pm$DZ;

5. DXDZ1 dx/dz for line joining the + on parallel side, + on perpendicular corners at z=$\pm$DZ;

6. DYDZ1 dy/dz for line joining the + on parallel side, + on perpendicular corners at z=$\pm$DZ;

7. X02 x at z=0 for line joining the - on parallel side, + on perpendicular corners at z=$\pm$DZ;

8. Y02 y at z=0 for line joining the - on parallel side, + on perpendicular corners at z=$\pm$DZ;

9. DXDZ2 dx/dz for line joining the - on parallel side, + on perpendicular corners at z=$\pm$DZ;

10. DYDZ2 dy/dz for line joining the - on parallel side, + on perpendicular corners at z=$\pm$DZ;

11. X03 x at z=0 for line joining the - on parallel side, - on perpendicular corners at z=$\pm$DZ;

12. Y03 y at z=0 for line joining the - on parallel side, - on perpendicular corners at z=$\pm$DZ;

13. DXDZ3 dx/dz for line joining the - on parallel side, - on perpendicular corners at z=$\pm$DZ;

14. DYDZ3 dy/dz for line joining the - on parallel side, - on perpendicular corners at z=$\pm$DZ;

15. X04 x at z=0 for line joining the + on parallel side, - on perpendicular corners at z=$\pm$DZ;

16. Y04 y at z=0 for line joining the + on parallel side, - on perpendicular corners at z=$\pm$DZ;

17. DXDZ4 dx/dz for line joining the + on parallel side, - on perpendicular corners at z=$\pm$DZ;

18. DYDZ4 dy/dz for line joining the + on parallel side, - on perpendicular corners at z=$\pm$DZ;

29 CTUB   *cut* tube, a tube cut at the extremities with planes not necessarily perpendicular to the z axis. It has 11 parameters:

1. `RMIN` inside radius;

2. `RMAX` outside radius;

3. `DZ` half length in z;

4. `PHI1` starting angle of the segment;

5. `PHI2` ending angle of the segment;

6. `LX` x component of a unit vector perpendicular to the face at `-DZ`;

7. `LY` y component of a unit vector perpendicular to the face at `-DZ`;

8. `LZ` z component of a unit vector perpendicular to the face at `-DZ`;

9. `HX` x component of a unit vector perpendicular to the face at `+DZ`;

10. `HY` y component of a unit vector perpendicular to the face at `+DZ`;

11. `HZ` z component of a unit vector perpendicular to the face at `+DZ`;

`PHI1` should be smaller than `PHI2`. If this is not the case, the system adds 360 degrees to `PHI2`.

Creation of a volume

    CALL **GSVOLU**   (CHNAME,CHSHAP,NMED,PAR,NPAR,IVOLU*)

Defines a volume with a given name, shape, tracking medium number and shape parameters.

CHNAME   (CHARACTER*4) volume name – it must be unique;

CHSHAP   (CHARACTER*4) name of one of the GEANT shapes;

NMED   (INTEGER) tracking medium number for the volume – if other volumes are positioned within this one, their tracking medium replaces the one of the mother;

PAR   (REAL) array containing the shape parameters;

NPAR   (INTEGER) number of parameters – if zero, then the volume must be positioned via the routine GSPOSP indicating the parameters for each copy (see [GEOM120]);

IVOLU   (INTEGER) internal volume number – if ≤ 0 an error condition has happened.

If one of the parameters expressing a length is negative, GEANT will try to maximise its value in each copy, without extending beyond the limits of the mother. This facility can be used in conjunction with the division of volumes using GSDVN, GSDVT, and GSDVX. Restriction apply to this facility:

  • the daughter should be positioned without a rotation matrix;

  • all shapes can be positioned within a similar shape with negative parameters, but only in the centre of the mother;

  • boxes with negative parameters can be positioned in: box, TRD1, TRD2 and TRAP with $\theta = \phi = 0$;

  • HYPE, ELTU and CTUB cannot have negative parameters;

  • PCON and PGON can only have 2 z planes.

Examples

        DIMENSION PECAL(3)
        DATA PECAL/1.71,4.,0.2/

        CALL GSVOLU('ECAL','BOX ',1,PECAL,3,IVOLU)

    CALL **GPVOLU**   (IVOLU)

Prints the volume parameters:

IVOLU (INTEGER) GEANT number of the volume to print – if IVOLU ≤ 0, all volumes will be printed;

Positioning a volume inside its mother

> CALL **GSPOS**   (CHNAME,NR,CHMOTH,X,Y,Z,IROT,CHONLY)

Places a copy of a volume previously defined by a call to GSVOLU inside its mother volume CHMOTH.

CHNAME   (CHARACTER*4) name of the volume being positioned;

NR   (INTEGER) copy number of the volume CHNAME being positioned;

CHMOTH   (CHARACTER*4) name of the volume in which copy NR of CHNAME is positioned;

X   (REAL) x position of the volume in the mother reference system;

Y   (REAL) y position of the volume in the mother reference system;

Z   (REAL) z position of the volume in the mother reference system;

IROT   (INTEGER) rotation matrix number describing the orientation of the volume relative to the coordinate system of the mother;

CHONLY   (CHARACTER*4) flag to indicate whether a point found to be in this volume may also be in other volumes which are not direct descendants of it – possible values are ONLY and MANY.

The following points are important for a correct use of GSPOS:

- the position and rotation with which a volume is positioned are relative to the mother reference system, that is to the reference system of the volume which contains the copy being positioned. To see how the reference system is defined for the GEANT shapes, see [GEOM050];

- GSPOS can be called several times with the same name, to place multiple copies of the same volume either in the same mother volume or in different ones. The copy number parameter NR is user defined, and it allows the different copies of the same volume to be distinguished. The user is free to assign any valid integer to this parameter. If two volumes are positioned with the same copy number, it will be impossible to decide in which one a particle is during tracking. If the same volume is positioned twice inside the same mother with the same copy number, the parameters of the second call to GSPOS will override the first ones for that copy;

- all the copies of a volume are identical: in particular they contain all the same daughters recursively – conversely, positioning a volume inside a mother will insert it in all the copies of that mother;

- the volumes mentioned in the call must be already defined by a call to GSVOLU;

- no volume can be positioned in a divided mother;

- in case of positioning without rotation, IROT should be set to 0 – note that this is faster than defining a unit matrix;

- the first volume, containing all the apparatus, cannot be positioned;

- if the CHONLY flag is equal to ONLY, the volume being positioned should not overlap with any other volume except his mother and his daughters and should not extend beyond the limits of its mother. In this case the search routines assume that, when a point is found in this volume, the only further searching required is in its contents. Other volumes at the same or higher levels or in separate branches will not be looked at. The first volume must be ONLY;

- if the `CHONLY` flag is set to `MANY`, a point found in this volume can also be in another volume at the same or higher level or in a different branch of the tree. To decide where a point is the following algorithm is applied:

  1. the tree is scanned *upward* until an `ONLY` mother with *positioned* contents (i.e. non-divided) is found;

  2. all the branches of the tree descending from this volume are scanned to find other volumes where the point may be;

  3. a winner is selected among the candidates according to the following rules:

     – if one of the candidates is `ONLY`, the point is declared in this volume. If more than one candidate is `ONLY` there is an error in the geometry definition;

     – amongst several `MANY` candidates, the one at the deepest level is chosen;

     – amongst several `MANY` candidates at the same level, the first one found is chosen;

  Although a considerable effort has been put in making sure that the `MANY` option works properly and caters for all the possible cases, still it introduces a considerable complication in the tracking and performance can be rather poor.

  Users should resort to this only when it is not possible to describe the experimental setup with `ONLY` volumes.

The data structure is so designed that, in any case, the parameters of a volume and the information about the number and position of its daughters are stored only once. This allows the creation of very complex geometries without correspondingly large storage requirements.

Positioning a volume inside its mother with parameters

```
CALL GSPOSP   (CHNAME,NR,CHMOTH,X,Y,Z,IROT,CHONLY,PAR,NPAR)
```

Position a copy of volume `CHNAME` inside its mother `CHMOTH` assigning its parameters.

CHNAME   (`CHARACTER*4`) name of the volume being positioned;
NR   (`INTEGER`) copy number of the volume `CHNAME` being positioned;
CHMOTH   (`CHARACTER*4`) name of the volume in which copy `NR` of `CHNAME` is positioned;
X   (`REAL`) x position of the volume in the mother reference system;
Y   (`REAL`) y position of the volume in the mother reference system;
Z   (`REAL`) z position of the volume in the mother reference system;
IROT   (`INTEGER`) rotation matrix number describing the orientation of the volume relative to the coordinate system of the mother;
CHONLY   (`CHARACTER*4`) flag to indicate whether a point found to be in this volume may also be in other volumes which are not direct descendants of it – possible values are `ONLY` and `MANY`;
PAR   (`REAL`) array of parameters for the volume being positioned;
NPAR   (`INTEGER`) number of parameters.

It is often the case in a detector to have a family of similar objects, differing only by their dimensions. A typical example are the crystals of an electromagnetic calorimeter. In this case it is convenient and logically consistent to give them all the same name, but assign to each copy a different set of parameters.

This can be done defining the volume with 0 parameters through the routine `GSVOLU` and then assigning the parameters to each copy via the routine `GSPOSP`.

`GSPOSP` is similar in all other aspects to `GSPOS` and the user is referred to the description of this routine for more information. An obvious limitation is that a volume defined with 0 parameters can only be positioned via `GSPOSP`, because otherwise its dimensions will be undefined.

Division of a volume into a given number of cells

> CALL **GSDVN**   (CHNAME,CHMOTH,NDIV,IAXIS)

Divide a volume in a given number of parts along a direction.

CHNAME   (CHARACTER*4) a unique name for the volume to be generated by subdivision of the mother volume;

CHMOTH   (CHARACTER*4) volume that has to be subdivided;

NDIV   (INTEGER) number of divisions into which the mother volume is to be divided;

IAXIS   (INTEGER) *axis* of the division.

The volumes resulting from a division are true volumes in the GEANT sense, with the only limitation that they cannot be positioned. They can have daughters and they can still be divided in turn. Different divisions are distinguished by a different division number, much the same as different copy of the same volume by the copy number. Every operation performed on a division cell (positioning or further division), is automatically propagated to all divisions cells of the same mother.

The kind of the division is indicated by the IAXIS argument. The allowed values of IAXIS and the resulting divisions are shown in figs. 25, 26, 27, 28, where the pictures in the first column correspond to an IAXIS value equal to 1, the second column to IAXIS = 2, and the third column to IAXIS = 3 respectivly. The basic constraint imposed by the GEANT geometry is that the result of a division is a volume which can be described in terms of the basic shapes.

The local coordinate system of the divisions is parallel to the system of the mother in case of divisions obtained by parallel planes or concentric divisions. In the case of parallel axes the coordinate system is shifted so that it is in the centre of the division. In case of ϕ divisions produced by planes passing through the axis of a volume with axial symmetry (TUBE, TUBS, CONE, CONS, PGON, PCON, SPHE), the local coordinate systems will be rotated so that the x axis passes through the centre of the division.

This routine allows the user to generate a large number of identical volumes filling a defined volume. The material of the slices is inherited from the mother.

It may happen that the different divisions of a volume have different dimensions. In this case, if a volume has to be positioned in each division, its dimensions must be different according to the division number. This can be obtained in some special cases giving to the dimension of the volume which has to vary in order to fit into the different mothers, the value of -1 in the call to GSVOLU which defines it. As explained in [GEOM050], GEANT will take care to assign to this dimension the maximum value in order to fill the current mother.

What can be done with division can be done also, in most cases, explicitly positioning all the copies. Users must be aware, however, that divisions offer the best performance in tracking of all GEANT geometrical constructs, and they should be used instead of positioning whenever possible in the definition of objects.

Division of a Volume into cells of a given size

This routine creates new volumes from a mother by divisions of a given step.

```
CALL GSDVT  (CHNAME,CHMOTH,STEP,IAXIS,NUMED,NDVMX)
```

CHNAME   (CHARACTER*4) a unique name for the volume to be generated by subdivision of the mother volume;

CHMOTH   (CHARACTER*4) volume that has to be subdivided;

STEP   (REAL) size of the divisions – this value can be in centimeters or degrees according to the value of IAXIS;

IAXIS   (INTEGER) *axis* of the division.

NUMED   (INTEGER) medium number of the divisions – this can be different from the one of the mother, as the division cells may leave a portion of the mother undivided (see below) – if NUMED $\leq$ 0 the medium of the mother;

NDVMX   (INTEGER) expected (maximum) number of divisions – if $\leq$ 0 or $>$ 255, 255 is assumed.

The full range of the mother will be divided in sections of the user supplied step. If the step is such that the mother cannot be divided exactly, the largest possible number of divisions will be generated, the excess space will be equally divided between each end of the range of the mother. These extra spaces will be assumed to belong to the mother.

For more information on the division in general, see [GEOM130].

Division of a volume - general case

> CALL **GSDVX**   (CHNAME,CHMOTH,NDIV,IAXIS,STEP,C0,NUMED,NDVMAX)

Divide a volume in a given number of parts along a direction, with a given step starting from an offset.

CHNAME   (CHARACTER*4) a unique name for the volume to be generated by subdivision of the mother volume;

CHMOTH   (CHARACTER*4) volume that has to be subdivided;

NDIV   (INTEGER) number of divisions into which the mother volume is to be divided;

IAXIS   (INTEGER) *axis* of the division.

STEP   (REAL) size of the divisions – this value can be in centimeters or degrees according to the value of IAXIS;

C0   (REAL) offset where division should start – this value can be in centimeters or degrees according to the value of IAXIS;

NUMED   (INTEGER) medium number of the divisions – this can be different from the one of the mother, as the division cells may leave a portion of the mother undivided (see below) – if NUMED $\leq$ 0 the medium of the mother;

NDVMX   (INTEGER) expected (maximum) number of divisions – if $\leq$ 0 or $>$ 255, 255 is assumed.

For more information on the division mechanism, see [GEOM130] and [GEOM140]. For the moment either NDIV or STEP must be set negative or 0, so that they will be computed from the CHMOTH's size. The case with both NDIV and STEP positive is not coded yet. It would permit leaving different gaps at both ends of the CHMOTH.

Provisionally the code consists of a call to either GSDVN2 or GSDVT2.

> CALL **GSDVN2**   (CHNAME,CHMOTH,NDIV,IAXIS,C0,NUMED)

Divide a volume in a given number of parts along a direction, starting from an offset.

CHNAME   (CHARACTER*4) a unique name for the volume to be generated by subdivision of the mother volume;

CHMOTH   (CHARACTER*4) volume that has to be subdivided;

NDIV   (INTEGER) number of divisions into which the mother volume is to be divided;

IAXIS   (INTEGER) *axis* of the division.

C0   (REAL) offset where division should start – this value can be in centimeters or degrees according to the value of IAXIS;

NUMED   (INTEGER) medium number of the divisions – this can be different from the one of the mother, as the division cells may leave a portion of the mother undivided (see below) – if NUMED $\leq$ 0 the medium of the mother;

The divisions start at the user specified coordinate value and extend to the end of the volume. The range from this offset to the upper coordinate limit of the mother volume will be divided into the supplied number of cells. In the case of ϕ division of a complete tube or cone, the whole 360 degrees will be divided into the user-supplied number of slices no matter what the origin is. Specifying an origin for the division, in this case, just moves the division boundaries. This can be useful to avoid a rotation. In all other cases the search routines will assume that a point is in the mother if the coordinate value is less than the value of the supplied offset.

```
CALL GSDVT2  (CHNAME,CHMOTH,STEP,IAXIS,CO,NUMED,NDVMX)
```

Divide a volume along a direction with a given step starting from an offset.

CHNAME   (CHARACTER*4) a unique name for the volume to be generated by subdivision of the mother
            volume;

CHMOTH   (CHARACTER*4) volume that has to be subdivided;

STEP   (REAL) size of the divisions – this value can be in centimeters or degrees according to the value
            of IAXIS;

IAXIS   (INTEGER) *axis* of the division;

CO   (REAL) offset where division should start – this value can be in centimeters or degrees according
            to the value of IAXIS;

NUMED   (INTEGER) medium number of the divisions – this can be different from the one of the mother,
            as the division cells may leave a portion of the mother undivided (see below) – if NUMED ≤ 0
            the medium of the mother;

NDVMX   (INTEGER) expected (maximum) number of divisions – if ≤ 0 or > 255, 255 is assumed.

The division start at the user-specified coordinate value and extend to the end of the volume. The range from
origin to upper coordinate limit of the mother volume is divided in sections of the user supplied step. If the
step is such that the range of the mother cannot be filled with cells, the largest possible number of cells is
created. The excess space up to the end of the mother volume will be assumed to belong to the mother.

In the case of ϕ division of a complete tube or cone, the whole 360 degrees will be filled with slices, no matter
what the origin is. Specifying an origin for the division, in this case, just moves the division boundaries.
This can be useful to avoid a rotation.

In all other cases the search routines will assume a point is just in the mother if the coordinate value is less
than the value of the user supplied origin.

The volume data structure – `JVOLUM`

1   The data structure `JVOLUM` and `JGPAR`

The meaning of the variables in the data structure `JVOLUM` shown in fig. 29 is the following:

`ISEARC`	search flag `[GEOM400]`, `[GEOM410]`:

        $=0$ volume positioning order or ordering by `GSNEXT/GSNEAR`;

        <0 binary search as defined by `GSORD`;

        >0 user ordering `GSUNEA/GUNEAR`;

`ISHAPE`	system shape number (see `[GEOM050]`;
`NIN`	number of volumes contained in the mother volume – if negative the volume is divided;
`NMED`	medium number for the volume;
`NPAR`	number of shape parameters;
`NATT`	number of attributes;
`PAR`	array of shape parameters;
`IAT`	array of attributes;
`IAXIS`	direction of the division (see `[GEOM130]`);
`IVO`	system volume number;
`NDIV`	number of divisions (`-NDVMX`, if computed dynamically, see `[GEOM140]`);
`CO`	coordinate value at which the division starts;
`STEP`	coordinate step for the division;
`NR`	user copy number;
`IROT`	rotation matrix number defining the orientation of the volume with respect to the mother reference system;
`X,Y,Z`	position of the volume with respect to the mother reference system;
`KONLY`	`ONLY/MANY` flag, see `[GEOM110]` for more information;
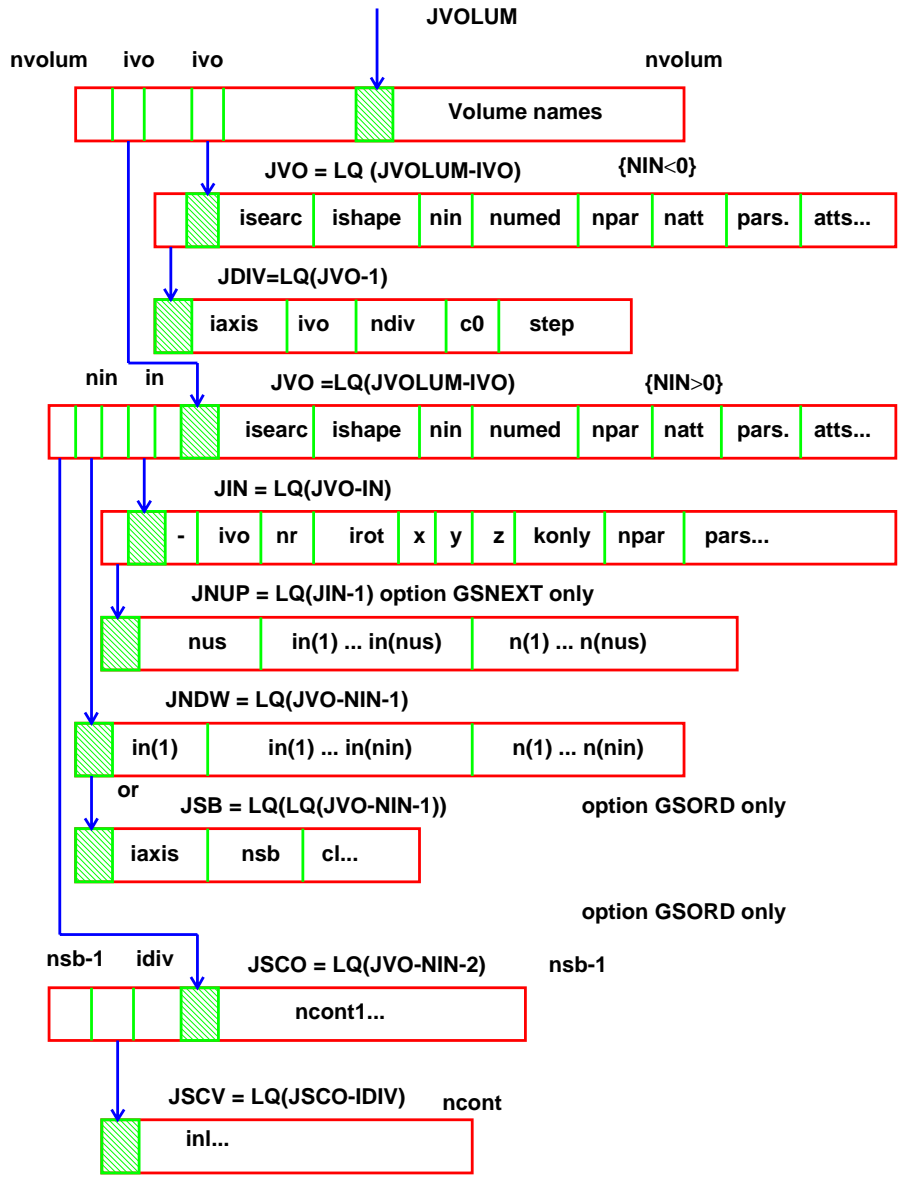

Figure 29: Example of geometrical tree structure

Rotation matrices

The relative position of a volume inside its mother is expressed in `GEANT` by a translation vector and a rotation matrix which are arguments of the routines `GSPOS` and `GSPOSP`. The rotation matrix expresses the transformation from the `Mother Reference System` to the `Daughter Reference System`.

A rotation matrix is described to `GEANT` by giving the polar and azimuthal angles of the axes of the `DRS` (x', y', z') in the `MRS` via the routine `GSROTM`.

> CALL **GSROTM**   (IROT,THETA1,PHI1,THETA2,PHI2,THETA3,PHI3)

IROT   (INTEGER) number of the rotation matrix;
THETA1   (REAL) polar angle for axis x';
PHI1   (REAL) azimuthal angle for axis x';
THETA2   (REAL) polar angle for axis y';
THI2   (REAL) azimuthal angle for axis y';
THETA3   (REAL) polar angle for axis z';
PHI3   (REAL) azimuthal angle for axis z'.

Stores rotation matrix `IROT` in the data structure `JROTM`. If the matrix is not orthonormal, it will be corrected by setting $y' \perp x'$ and then $z' = x' \times y'$. A warning message is printed in this case.

Note: the angles THETA and PHI must be given in degrees.

Examples of use

The unit matrix is defined in the following way:

$$
\left.\begin{array}{c} x' \parallel x \\ y' \parallel y \\ z' \parallel z \end{array}\right\} \Rightarrow \left\{\begin{array}{lll} \theta_1 = 90° \; ; & \phi_1 = 0° \\ \theta_2 = 90° \; ; & \phi_2 = 90° \\ \theta_3 = 0° \; ; & \phi_3 = 0° \end{array}\right.
$$

This is just an example. There is in fact no need to define a unit rotation matrix. Giving the value 0 to the rotation matrix number in the call to `GSPOS` and `GSPOSP` is equivalent to a positioning without rotation and it improves tracking performance.

The result of a 90° counterclockwise rotation around z, followed by a 90° counterclockwise rotation around the new x is a cyclic shift of the axes: $x \to z'$, $y \to x'$, $z \to y'$. This is expressed by the following rotation matrix:

$$
\left.\begin{array}{c} x' \parallel y \\ y' \parallel z \\ z' \parallel x \end{array}\right\} \Rightarrow \left\{\begin{array}{lll} \theta_1 = 90° \; ; & \phi_1 = 90° \\ \theta_2 = 0° \; ; & \phi_2 = 0° \\ \theta_3 = 90° \; ; & \phi_3 = 0° \end{array}\right.
$$

Sometimes the rotation matrix is known or it can be constructed. In this case the arguments to the routine `GSROTM` can be calculated with the help of the routine `GFANG` in the following way:

```
      DIMENSION ROTMAT(3,3), ROWMAT(3), PHI(3), THETA(3)
      LOGICAL ROTATE
      .
      .
      .
      DO 10 I=1,3
         ROWMAT(1) = ROTMAT(I,1)
         ROWMAT(2) = ROTMAT(I,2)
         ROWMAT(3) = ROTMAT(I,3)
         CALL GFANG(ROWMAT,COSTH,SINTH,COSPH,SINPH,ROTATE)
         THETA(I) = ATAN2(SINTH,COSTH)
         PHI(I)   = ATAN2(SINPH,COSPH)
  10  CONTINUE
      .
      . {\sl Transform to degrees}
      .
      CALL GSROTM(IROT,THETA(1),PHI(1),THETA(2),PHI(2),THETA(3),PHI(3))
```

CALL **GPROTM** (IROT)

Prints the rotation matrix elements and angles.

IROT (INTEGER) rotation matrix number: if IROT=0 all rotation matrixes will be printed, if IROT<0, matrix number |IROT| will be printed without header information.

The rotation matrix data structure `JROTM`
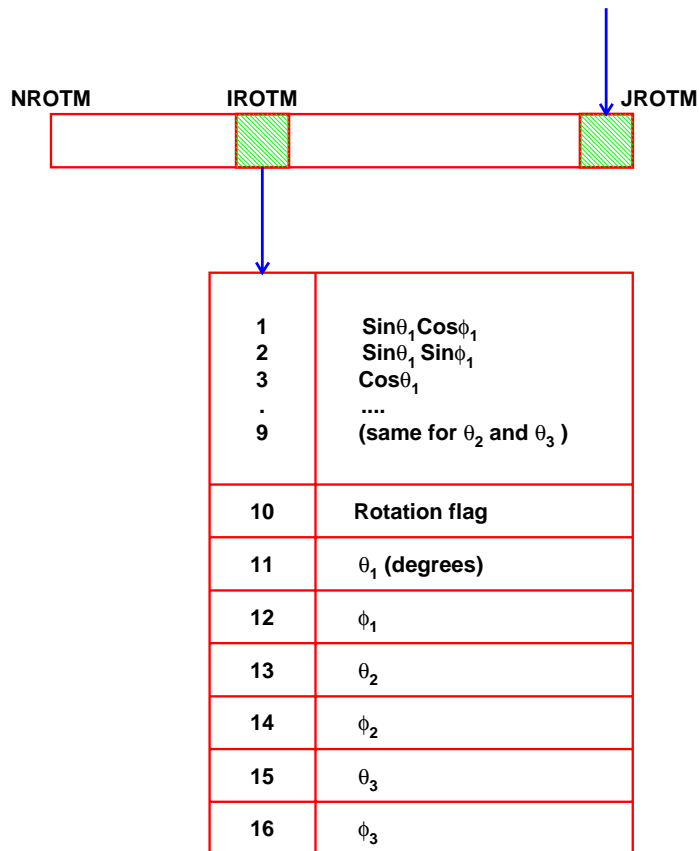

Figure 30: Layout of the `JROTM` data structure

`JR = LQ(JROTM-IROTM)` is the pointer to the bank of the rotation matrix `IROTM`;

The rotation flag is computed by `GSROTM` to recognise simple rotation configurations. In particular it is set to 0 for the unit matrix.

Finding in which volume a point is

CALL **GMEDIA**   (X,NUMED*)

X   (REAL) array of dimension 3 with the coordinates in the MRS;
NUMED   (INTEGER) medium number, if this is zero the point is outside the detector.

Searches the geometrical tree structure to find in which volume the point X is. The tracking medium is returned in NUMED, and the common /GCVOLU/ is updated.

GMEDIA uses the geometry data structure to conduct its search starting its search from the last volume where a point was found. If no previous search has been conducted, the first volume is used as a starting point.

If the point is not inside the current volume, GMEDIA looks in its mother and so on, until it finds a volume which contains the point. It then looks at the contents of this object and so on until the point is in a volume but in none of its contents (if any).

If this *downward* search terminates in a 'MANY' object, GMEDIA looks for another candidate. See [GEOM110] for a description of the 'MANY' volumes tratment.

The *physical* geometrical tree from the first volume to the current one is stored in the common block GCVOLU (see [ZZZZ010]) and in the structure JGPAR (see [GEOM199]).

CALL **GTMEDI**   (X,NUMED*)

X   (REAL) array of dimension 3 with the coordinates in the MRS;
NUMED   (INTEGER) medium number, if this is zero the point is outside the detector.

This routine performs the same function than GMEDIA, but it uses the dynamical information of the particle history to speed-up the search:

- when INWVOL=2 (common /GCTRAK/) the particle just came out of a volume. In this case, if INFROM (common /GCVOLU/) is positive, it is interpreted by GTMEDI as the number IN of the content just left, inside the mother volume where the point X is assumed to be. This content will not be searched again.

- the daughter of the current volume which limits the geometrical step of the particle (i.e. where the particle would be heading moving along a straight line) is searched first. INGOTO (common /GCVOLU/) is set by GTNEXT, to transmit the information on this one volume which has limited the geometrical step SNEXT as follows:

  >0 IN^{th} content;
  $=0$ current volume;
  <0 -NLONLY, with NLONLY defined as the lowest 'ONLY' level up in the tree which is an ancestor of the 'MANY' volume where the point X is.

CALL **GINVOL**   (X,ISAME*)

X   (REAL) array of dimension 3 with the coordinates in the MRS;
ISAME   (INTEGER) return flag.

Checks if particle at point X has left current volume. If so, returns ISAME = 0 and prepares information useful to identify the new volume entered, otherwise, returns ISAME = 1.

Finding distance to next boundary

```
CALL GNEXT  (X,SNEXT*,SAFETY*)
```

```
CALL GTNEXT  (X,SNEXT*,SAFETY*)
```

Finds distance to the next boundary. It takes explicit account of shape content and uniqueness.

X   (`REAL`) array of 6 of coordinates and direction cosines;
SNEXT   (`REAL`) distance to the nearest volume boundary along the particle direction;
SAFETY   (`REAL`) *safety* distance, that is smaller distance to any boundary;

This routine evaluates the two *distances* which are needed by the `GEANT` tracking routines. `GTNEXT` and `GNEXT` perform the same function, but `GNEXT` is a static routine which can be called by the user, while `GTNEXT` is the routines used internally by `GEANT` during tracking, and it should not be called by the user.

If `INFROM` (common `/GCVOLU/`) is different from 0, `GTNEXT` interprets it as the daughter out of which the particle just came, and uses the list of daughters stored with that volume, possibly modified by `GSNEXT`/`GSNEAR` to calculate the distance to the next boundary.

The first action of `GTNEXT` is to calculate the `SAFETY` distance. If this is larger than the current step candidate, no other calculation is performed and the `IGNEXT` flag (common `/GCTRAK/`) is set to 0, indicating that no change of volume is occurring at the end of the current step. If the step is smaller than safety, then `SNEXT` is computed. If the step is smaller than `SNEXT`, again there will not be any change of volume during the step and `IGNEXT` is set to 0. If on the contrary the candidate step is larger than `SNEXT`, a change of volume will occur at the end of the step, and `IGNEXT` is set to 1 and `INGOTO` (common `/GCTRAK/`) is set to the number of the daughter where the particle is entering, if any.

Charged particles in magnetic field are transported with a similar logic. However, even if the candidate step is smaller than `SNEXT`, the particle can still cross into another volume due to its bent path. When tracking in magnetic field, after every step greater than `SAFETY` it is checked whether the particle is still in the same volume. If this is not the case, the step is divided by two and transport is tried again. Conversely a charged particle in magnetic field may still be in the current volume even after having travelled the distance to the nearest boundary along a *straight* line. So boundary crossing is declared only when `IGNEXT` is different from 0 and the difference between the real trajectory and the bent one is smaller than `EPSIL` (common `/GCTMED/`).

Reference system transformations

```
   CALL GMTOD   (XM,XD*,IFLAG)
```

XM   (`REAL`) array of 3 containing the input position (`IFLAG=1`) or direction cosines (`IFLAG=2`) in
            the Master Reference System;

XD   (`REAL`) array of 3 containing the output position (`IFLAG=1`) or direction cosines (`IFLAG=2`) in
            the (current) Daughter Reference System;

IFLAG   (`INTEGER`) transformation flag:

    1   input is a position, it must be translated and rotated;
    2   input is a direction, it must be rotated.

This routine transform coordinates or directions from the `MRS` to the reference system of the current volume.
The `/GCVOLU/` must be properly filled, either by the tracking routines, by `GMEDIA` or by `GLVOLU`.

```
   CALL GDTOM   (XD,XM*,IFLAG)
```

Performs the inverse operation to `GMTOD`.

Pseudo-division of a volume

```
   CALL GSORD  (CHNAME,ICORD)
```

CHNAME (CHARACTER*4) name of the volume;
ICORD (INTEGER) direction of the pseudo-divisions:

    1   x;
    2   y;
    3   z;
    4   cylindrical R ($\sqrt{x^2 + y^2}$);
    5   spherical ρ ($\sqrt{x^2 + y^2 + z^2}$);
    6   ϕ, azimuthal angle;
    7   θ, polar angle with respect to the z axis.

This routine sets the search flag (`Q(JV0+1)`) of volume `CHNAME` to `-ICORD`. When the definition of the geometry is complete and `GGCLOS` is called, this flag is interpreted as a request to order the content of `CHNAME` along *axis* `ICORD`. This operation is performed by the routine `GGORD`. `GGORD` computes the limits of each of the contents along the given coordinate axis (see [GEOM001]), and prepares the lists of contents in each of the sections defined by the neighbouring coordinate. The `JVOLUM` structure is extended, for the mother volume, with banks which contains the list of boundaries and the lists of contents, so as to permit a binary search to access the contents of interest. The coordinates are in the local system of the mother volume. The routine `GGORD` will not be called if the number of contents exceeds 500.

The actual effect of this routine depends on the setting of the `IOPTIM` variable in the common `/GCOPTI/`. `IOPTIM` is controlled by the data record `OPTI` or the interactive command with the same name. The meaning of the different values of `IOPTIM` is the following:

<0 no call to `GGORD` will be made, irrespective of the value of `ISEARCH`;

  0   `GGORD` will be called for those volumes for which `GSORD` has been called;

  1   for all volumes with contents for which neither `GUSEAR` nor `GSORD` has been called, the routine `GGORDQ` will be called;

  2   `GGORDQ` is called for all volumes with contents for which `GUSEAR` has not been called.

`GGORDQ` orders the contents along all the possible axes and choses the ordering which provides the lowest number of volumes per division.

Ordering the contents of a volume

In the case of a mother volume containing a large number of daughters, tracking can be rather slow. This is due to the fact that each time `GEANT` requires to know in which daughter it is or will be tracking, it search through the whole list of daughter volumes. This is done by `GEANT` creating for every daughter volume a list which contain pointers to all the daughters of the same mother.

Clearly this may be avoided, because at any step of tracking, the coordinates and direction cosines of the current step are known. From this and the knowledge of the geometry, a restricted list of daughter volumes to be searched can be built. This can be accomplished in `GEANT` in two ways, which are described in this chapter.

Note: the user must be aware that the following routines alter the default search list of daughters of a given mother. A user mistake can cause wrong transport because `GEANT` does not make any check on the correctness of the list of neighbours provided by the user.

Static ordering

      CALL **GSNEXT**   (CHMOTH,IN,NLIST,LIST)

CHMOTH   (CHARACTER*4) name of the mother volume to be ordered;
IN   (INTEGER) number of the content for which a list is established;
NLIST   (INTEGER) number of neighbours to be considered during tracking;
LIST   (INTEGER) list of neighbours to volume IN.

This routine stores a given ordered `LIST` of `NLIST` daughter volumes to search when leaving the IN^{th} daughter of the mother volume `CHMOTH`.

If `IN=0`, for each content, `GSNEXT` builds a list limited to the contents `IN+1` (if it exists), `IN-1` (if it exists) and `IN` itself.

      CALL **GSNEAR**   (CHMOTH,IN,NLIST,LIST)

CHMOTH   (CHARACTER*4) name of the mother volume to be ordered;
IN   (INTEGER) number of the content for which a list is established;
NLIST   (INTEGER) number of neighbours to be considered during tracking;
LIST   (INTEGER) list of neighbours to volume IN.

This routine stores a given ordered `LIST` of `NLIST` daughter volumes to search when leaving the IN^{th} daughter of the mother volume `CHMOTH`.

If `LIST(1)=0` the particle is back into the mother when leaving the IN^{th} daughter. This means that the IN^{th} is not contiguous to any other daughter or to the boundary of the mother.

If `IN=-1`, the mother does not have contents contiguous to its boundaries (status bit 4 set in mother volume bank for action in `GGCLOS`).

If `IN=0` for each content `GSNEAR` sets `LIST(1)=0`.

`GSNEAR` must be called after all contents have been position (except when `IN=-1`)

Dynamic ordering

The list of neighbours to search when exiting from the IN^{th} content may depend also on the direction and position of the particle. In case where it is necessary, for performance reasons, to exploit also this information, GEANT offers the possibility to the user to build a dynamic search list.

> CALL **GSUNEA** (CHNAME,ISEARC)

CHNAME (CHARACTER*4) name of the volume where the user search has to be activated;
ISEARCH (INTEGER) specifies the kind of search list to be used: a positive value must be specified with this routine to activate user search lists.

This routine should be called once for every volume where user volume search is activated.

> CALL **GUNEAR** (ISEARC,ICALL,XC,JNEAR)

ISEARCH (INTEGER) number associated to the volume in which the user search is used, it is the same number set by the user with GSUNEA;
ICALL (INTEGER) type of question that the list of volumes must answer:

  1 GMEDIA-like call, where am I?
  2 GTNEXT-like call, where can I go?

XC (REAL) array of 6 containing the position and the direction cosines of the particle (x, y, z, p_x/p, p_y/p, p_x/p);
JNEAR (INTEGER) pointer to the volume list bank which has to be filled by the user;

The list of volumes where GEANT has to search to answer the question specified by ICALL is returned by the user starting at Q(JNEAR+1. GEANT will only look at the volumes specified by the user and in the order in which they appear in the list. Daughters are numbered from 1 to N according to the order with which they have been positioned in the mother. The list should be filled in the following way:

 IQ(JNEAR+1) = N, number of volumes in the list
 IQ(JNEAR+1+1) = number of the first daughter to search
 IQ(JNEAR+1+2) = number of the second daughter to search
 .
 .
 .
 IQ(JNEAR+1+N) = number of the Nth daughter to search

The user should be aware that this routine is called very often, almost at every tracking step, so it should be coded with the maximum efficiency in mind. An example of GUNEAR could be the following:

```
      SUBROUTINE GUNEAR(ISEARC,ICALL,XC,JNEAR)
*---              Make sure to add GEANT main store
+SEQ, GCBANK.
      DIMENSION XC(6), MYLIST(100)
*---              Executable code
      IF(ISEARC.EQ.1) THEN
*---              Build a list using XC and ISEARC for a GMEDIA type call
*---              Put all the daughters where the particle may be in
         MYLIST(1) = ....
         .
         .
         .
         MYLIST(N) = ....
      ELSE
```

```
*---               Build a list using XC and ISEARC for a GTNEXT type call
*---               Put all the daughters where the particle may be going
      MYLIST(1) = ....
         .
         .
         .
      MYLIST(N) = ....
      ENDIF
*---               Return the information to GEANT
      DO 10 I=1,N
         IQ(JNEAR+1+I) = MYLIST(I)
  10  CONTINUE
      IQ(JNEAR+1) = N
*---               End of GUNEAR
      END
```

Volume attributes

```
    CALL GSATT  (CHNAME,CHIATT,IVAL)
```

CHNAME   (CHARACTER*4) volume name;
CHIATT   (CHARACTER*4) attribute to be set;
IVAL   (INTEGER) value to which the attribute is to be set.

Changes the attribute CHIATT of the volume called CHNAME to the value IVAL. The names and meaning of the attributes and their allowed values are:

Number	Name	Description	
1	WORK	0	inactive volume
		1	active volume
2	SEEN	-2	only the volume is visible, but none of its descendants
		-1	the volume is not visible together with all its descendants
		0	the volume is not visible
		1	the volume is visible
3	LSTY	line style parameter (see [XINT002])	
4	LWID	line width parameter (see [DRAW400])	
5	COLO	area filling colour (see [XINT002])	
6	FILL	area filling resolution (see [DRAW400])	
7	SET	set number associated to the volume	
8	DET	detector number associated to the volume	
9	DTYP	detector type associated to the volume (1,2)	
10	NODE	dummy	

```
    CALL GFATT  (CHNAME,CHIATT,IVAL*)
```

Returns in IVAL the attribute CHIATT of the volume CHNAME. The arguments have the same meaning than for the routine GSATT.

```
    CALL GFPARA  (CHNAME,NR,INTEXT,NPAR*,NATT*,PAR*,ATT*)
```

CHNAME   (CHARACTER*4) volume name;
NR   (INTEGER) copy number;
INTEXT   (INTEGER) type of volume parameters requested:
            0   user parameters;
            1   internal parameters;
NPAR   (INTEGER) number of parameters returned;

`NATT`   (`INTEGER`) number of attributes returned;

`PAR`   (`REAL`) array of parameters;

`ATT`   (`REAL`) array of attributes.

Returns parameters `PAR(1...NPAR)` and attributes `ATT(1...NATT)` for the volume `CHNAME` with copy number `NR`.

User initialisation of the common block `/GCVOLU/`

```
    CALL GLVOLU  (NLEV,LNAM,LNUM,IER*)
```

`NLEV`   (`INTEGER`) number of levels to fill;

`LNAM`   (`INTEGER`) array of `NLEV` volume names stored via the `UCTOH` routine;

`LNUM`   (`INTEGER`) array of `NLEV` volume copy (or division) numbers;

`IER`   (`INTEGER`) returns code different from 0 in case of error, a diagnostic is also printed;

This routine fills the volume parameters in common `/GCVOLU/` for a physical tree, specified by the lists `LNAM` and `LNUM` of volumes names and numbers, and for all its ascendants up to level 1.

The routine is optimised and does not re-compute the part of history already available in `GCVOLU`. This means that if it is used in user programs outside the usual framework of the tracking, the user has to initialise to zero `NLEVEL` in common `GCVOLU`.

An example of use of `GLVOLU` in this context could be to find the position and direction of a particle in the local coordinate system of a volume:

```
      .
      .
+SEQ,GCVOLU
      DIMENSION LNAM(15), LNUM(15), POS(3), DIR(3), POSL(3), DIRL(3)
      .
      .
      CALL UCTOH('MOTH',LNAM(1),4,4)
      LNUM(1) = 1
      CALL UCTOH('CAL1',LNAM(2),4,4)
      LNUM(2) = 2
      CALL UCTOH('MOD1',LNAM(3),4,4)
      LNUM(3) = 5
      CALL UCTOH('CHAM',LNAM(4),4,4)
      LNUM(4) = 18
*---
      NLEVEL  = 0
      CALL GLVOLU(4,LNAM,LNUM,IER)
*---
      CALL GMTOD(POS,POSL,1)
      CALL GMTOD(DIR,DIRL,2)
      .
      .
```

Medium search statistics

In order to understand the behaviour and the performance of the geometry defined by the user, it is sometimes very useful to accumulate the statistic of the various geometrical routines called. This is done automatically by `GEANT` if the statistical package is activated via the data record `STAT 1`. In this case the routine `GBSTAT` is called by `GGCLOS`, `GFSTAT` is called by the tracking routines `GINVOL`, `GTMEDI`, `GTNEXT`, `GTRACK` and `GMEDIA` to accumulate the statistics and `GPSTAT` is called by `GLAST`.

CALL **GBSTAT**

Creates the data structure `JGSTAT` in order to accumulate statistics for the number of calls to routines `GINVOL`, `GTMEDI`, `GTNEXT`, `GTRACK` and `GMEDIA` and the total number of steps per volume.

CALL **GPSTAT**

Prints the volume statistics accumulated during the run. The table which is printed is useful for optimizing the tracking medium parameters associated to each volume.

CALL **GFSTAT**

Fills banks for volume statistics.

An example of output is the following:

```
********************************************************************************************************
*                                                                                                      *
*                                  V O L U M E    S T A T I S T I C S                                  *

End of geometry definition

CALL **GGCLOS**

This routine should be called after all volumes, positions, hits and digits have been defined. Its action is confined to clean up the volume banks and to take any action required by the ordering techniques.

`GGCLOS` performs all the requested geometry optimisation, included the creation of pseudo-divisions in volumes flagged by `GSORD`. It performs the local development of tha last leaves of the geometrical tree, where applicable.

It also calls the routine `GGDETV` which prepares the prototype lists of volume names and maximum multiplicities which permit to identify uniquely any sensitive detector whose generic name has been declared through the routine `GSDETV` (and not `GSDET`) [HITS001].

`GGCLOS` must be called also after reading a geometry data structure from disk.

The CADINT Interface

1 Introduction

The engineering work in HEP for design, analysis and manufacturing of detectors requires Computer Aided Engineering (CAE) tools. To ensure coherent design the same detector descriptions should be used by physicists, engineers and, eventually, manufacturers. Efficient exchange of data between CAE tools and `GEANT` becomes crucial.

The CADINT interface allows to export detector models from `GEANT` to Computer Aided Design (CAD) systems. CADINT outputs detector models in the SET (Standard d'Echange et de Transfert) [1] neutral file format. A detector model is written as an assembly of solid volumes, with respect to a global coordinate system. The geometric representation used is Constructed Solid Geometry (CSG) [2].

A `GEANT` detector geometry exported through CADINT into a CAD system can be used to check the coherence of the model used in simulation. The CADDFAS service at CERN can be used to convert SET files into IGES (Initial Graphics Exchange Specification, an American standard for exchange of CAD data) [3] format, which is readable by most CAD systems. For more information about the CADDFAS service, send an e-mail to *caddfas@cadd.cern.ch* with subject: *info*

2 SET File Format

SET is a French standard to exchange and archive CAD data. It was developed as a neutral file format for exchanging data between different CAD systems at Aerospatiale in 1983. The aim was to develop a more reliable alternative to IGES. It became an official French standard, Afnor Z68-300, SET, in 1985. SET was revised and extended in 1989. The version (89-06) used in CADINT, supports wireframe, surface and solid entities. Entities for drafting and connectivity applications, as well as scientific data and FEM (Finite Element Method) modelling are also included. The philosophy behind the standard is that it should be able to handle the complete information that may occur. It is also considered to be important to have an unambiguously defined format, that is compact in size, and is flexible enough to handle future demands from the CAD/CAM industry.

The structure of SET is based upon a three level hierarchical structure, which consists of data assemblies, data blocks, and data sub-blocks. Information that is common to several blocks or assemblies, is stored in a so-called dictionary.

- **Assembly:** A SET data assembly is a collection of data defining a certain piece of information, such as a mechanical part. A SET file can contain one or more data assemblies;

- **Block:** In the nomenclature of the SET files, the blocks are identified by an @, followed by the number of the block identifying its type. This number is followed by the block's reference number in the file. (i.e. in a file with n blocks, the block sequence numbers will be from 0 to n.) After this, sub-blocks and dictionary entries used in the block follows. A SET data block is an elementary entity, which consists of definition or control data that are used in different applications. Such entities could be geometric objects as points or lines, or other entities like matrices, drawings and views or SET file identifiers;

- **Sub-block:** A sub-block consists of an identifier, and a list of data that contributes to the description of the entity defined by the data block. The different parameters inside a sub-block, such as coordinates, are represented by their values. A sub-block has the identifier "#", followed by its type number, possible references to the dictionary, and parameters applicable in the sub-block;

- **Dictionary:** The dictionary is a set of predefined parameters in the specifications of the standard. They are accessible as dictionary entries which are assigned an identifier (a colon "**:**" and the dictionary number), and a precise meaning given by authorised and/or default values.

References among entities in a SET file are made by using pointers, either directly from the blocks, or via sub-blocks or dictionary entries. Pointers to other blocks are identified by an "**!**", followed by the sequence numbers of the blocks. SET has no unique mapping of sub-block types and dictionary entries into blocks. Several combinations are allowed for each different block. Definitions of possible combinations and guidelines for implementation are given in the SET standard [1].

3 Implementation

In the CADINT interface, a user can indicate a subtree of a detector by giving the name of a volume. All the contents of this volume will be written into a SET file. A user can also choose the contents by setting the daughter volumes visible or invisible using the visibility attribute. Only the visible volumes will be written into the SET file. In order to avoid repeated volumes, a number of divisions can be chosen. The rest of the divisions can be reproduced in a CAD system, if needed. The colors of volumes defined by the GEANT color attribute are also transmitted into SET files.

The CADINT interface writes the geometry of a GEANT detector model in the SET file format in two basic phases:

1. write the volume information;
2. write the position information.

The interface writes volumes into the SET format as CSG solids i.e. the volumes are created using extrusions, revolutions, ruled solids, rectangular parallelepipeds, etc. Divisions are written as normal volumes. Every division of a divided volume is a distinct volume in a SET file. An index is attached to the end of the name of each of the divisions in order to distinguish each division instance. The indexing of instances is reset in each division. An index is attached to the end of the volume name of multiple copies of normal volumes as well.

In SET format, a volume must be first written, after that it can be positioned. All volumes are positioned with respect to the global coordinate system. Thus, the tree structure in the SET file is flat. There will be overlaps between volumes, since no Boolean operations are used to define the tree structure. However, the tree structure is written into a separate file. The material information is written into this same text file.

The interface decodes the JVOLUM data structure and computes the necessary parameters if needed (negative parameters, dimensions of divisions, etc.). These computations are based on the GEANT drawing routines. The interface decodes a detector model starting from the global mother volume. After that it decodes the first daughter volume in the left side of the tree. The daughter volume can be a normal volume or a division. It continues decoding daughter volumes until it is at the bottom of the tree. After that the interface returns one level and decodes the next daughter of the current volume if any exists. In a case of a divided volume, the divisions are treated in the same way as the daughter volumes. The creation of the SET file is performed simultaneously.

3.1 Volume Information

The tree decoding routine transfers the volume information during decoding to the relevant shape routine which writes the volumes into the SET file. Every different shape has its own routine. For example, the simplest shape, BOX, is written in the SET format as follows:

```
@50,N1,:5,2#60,X,Y,Z
@302,N2#317,-DX,-DY,-DZ
@100,N3,:5,2,:9,'Name'#101,!N1,!N2
```

Where

- `@50` is the block number which defines a primitive solid;
- `N1,N2,N3` are the sequence numbers of each block;
- `:5,2` is the dictionary entry number which gives a total subordination to one block;
- `#60` is the sub-block number which defines the geometric parameters of a solid rectangular parallelepiped;
- `X,Y,Z` are the dimensions of the rectangular parallelepiped;
- `@302` is the block number for geometric transformation;
- `#317` is the sub-block number for translation;
- `DX,DY,DZ` are the coefficients of the translation;
- `@100` is the block number which defines a constructed solid;
- `:9` is the dictionary entry number for a name associated with the block;
- `Name` is the name of the volume;
- `#101` is the sub-block number for transformation operation.

The rectangular parallelepiped is first defined with the given parameters. Then the translation of coordinates is defined. The translation is necessary since GEANT and SET use origins in different places. Finally, the transformation operation is defined for a constructed solid which in this case is the translation of the coordinates of a primitive solid. The GEANT shapes are converted to SET as follows:

SHAPE	DEFINITION IN SET
BOX	rectangular parallelepiped
TRD1	ruled solid between 2 faces
TRD2	ruled solid between 2 faces
TRAP	ruled solid between 2 faces
TUBE	solid of revolution of a face
TUBS	solid of revolution of a face
CONE	solid of revolution of a face
CONS	solid of revolution of a face
SPHE	sphere
PARA	ruled solid between 2 faces
PGON	first segment ruled solid, other segments copied and rotated, finally boolean union for all the segments
PCON	solid of revolution of a face
ELTU	solid of linear extrusion of a face
HYPE	not implemented
GTRA	ruled solid between 2 faces
CTUB	solid of revolution and boolean subtraction by 2 half-spaces

3.2 Position Information

The position information of a volume is handled by a routine, which writes the coordinates and the rotation matrix. The tree decoding routine transforms the coordinates and the rotation matrix of a volume to the global coordinate system, and then transfers the data to the routine which writes the translation and rotation of a volume into the SET format as follows:

```
@302,N1#301,M1,M2,M3,M4,M5,M6,M7,M8,M9,XC,YC,ZC
@100,N2,:9,'Name'#101,!N1(of the shape),!N1
```

Where

- `@302` is the block number for geometric transformation;
- `N1,N2` are the sequence numbers of each block;
- `#301` is the sub-block number which defines the coefficients of the rotation-translation matrix;
- `M1...M9` are the coefficients of the rotation matrix;
- `XC,YC,ZC` are the components of the translation vector;
- `@100` is the block number which defines a constructed solid;
- `:9` is the dictionary entry number for a name associated with the block;
- `Name` is the name of the volume;
- `#101` is the sub-block number for transformation operation;
- `!N1` is the reference to sequence number of the mother volume.

The geometric transformation is first defined with the given parameters and then the transformation operation is defined for a constructed solid. The principle of writing divisions into the SET format is equivalent to the case of normal volumes.

3.3 Material and Tree Information

The material file is written into a separate file simultaneously with the SET file. It contains information on tracking medium, material and density for each defined volume. The GEANT tree is written into this same file. After the volume name there follows the number of daughters and daughter names. In a case of divided volume, the negative number of divisions is given after the name of the divided volume, and followed by the offset, step and the name of the division instance. An output of a material file of a GEANT example program:

```
GEANT-SET MATERIAL LISTING FILE
-------------------------------
Materials in the geometry described in
the .SET file:  gexam4.set

Volume name  Tracking media   Material       Density

CALO          1 AIR           1 AIR          0.12000001E-02

4 Usage

In order to carry out a successful transfer of a detector model, a user needs to be aware of certain limitations of the interface. The user is recommended to communicate with the engineers using CAD systems to establish a proper transfer methodology. If a CAD system is not capable of receiving the whole detector geometry in a single SET file, a user can transfer a detector model in smaller parts. These parts can then be joined together in the CAD system. Normally it is a good idea to just export one instance of each division in order to limit the number of exported volumes. The divisions can be reproduced in CAD systems. It is impossible to give an exact size-limit for a detector model which can be transferred in one file, because the limitation depends on the structure of the detector model.

The `GEANT` graphics package provides excellent capabilities for viewing parts of a detector model which is to be exported. Using the visibility attribute and the number of division instances, a user will be able to see what is to be exported. A user can use different colors in order to help to distinguish different volumes (eg division instances, etc.) in a CAD system. Dummy volumes, such as mothers made of air or vacuum should be suppressed using the visibility attribute, since the interface is currently not able to discard such information. A user must remember to specify the drawing parameters again if he wants to draw the detector model after using the interface. This is because the interface uses modified drawing routines.

A plot of the `GEANT` tree can be useful for engineers to understand the structure of the `GEANT` detector model. `GEANT` volume names are useful references regarding the material and tree information. The tree information is also provided in the material file, but a graphical presentation is often useful.

GEOM Bibliography

The detector response package

1   Introduction

In the context of `GEANT`:

- **hit** is the user-defined *information* recorded at tracking time to keep track of the interaction between one particle and a given detector, and necessary to compute the digitisations later.

- **digitisation** (*digit*) is the user-defined `information` simulating the response of a given detector element, usually estimated after tracking a complete event.

The detector response package consists of tools to store, retrieve or print the information relevant to hits and digitisation which is in the data structures `JSET, JHITS` and `JDIGI`. A few subroutines which may help the user to solve some of the usual digitisation problems in simple detectors have been added to the package, e.g. the intersection of a track with a plane or a cylinder and the digitisation of conventional drift and `MWP` chambers.

For complex setups with different types of detectors the user has normally to define several types of hits and digitisations. In addition to the hits generated by all particles of the current event, computing the digitisations requires usually some information about the intrinsic characteristics and performance of the detectors. The information to be recorded for the hits and digitisations is highly experiment dependent, therefore only a framework can be proposed to store it.

Two remarks can be made:

- during the life of an experiment, the stability of the format and content of the information to be stored is usually reached much earlier for the hits than for the digitisations. Therefore the user may save computing time by designing an intermediate event output at the hits level.

- the scheme proposed for storing the digitisations should in any case be considered as an intermediate stage, a further processing of the data being necessary if the user wants to simulate more closely the specific format of the real data-acquisition system.

2   `SET`s and `DET`ectors

The reader is assumed to be familiar with the way the geometrical setup is described (`[GEOM]`), in particular with the concepts of logical and physical volume tree structure.

The user is required to classify into sets all sensitive detectors (defined as those volume defined as detector via `GSDET/GSDETV`) for which he wants to store hits in the data structure `JHITS`. The 4-character names which identify the sets are user defined, and the list of sets which the user wants to activate for a given run can be entered through the data record `SETS`. The user can group together in one or in several sets detectors of the same or different types. For convenience, it is recommended to have at least one set for each main component of the setup, e.g. hadronic calorimeters, electromagnetic calorimeters, vertex chamber, etc.

A volume can be declared as a sensitive detector through the tracking medium parameter `ISVOL`, and allocated to a set through the subroutine `GSDET` or `GSDETV`. Each (logical) sensitive detector is identified by the 4-character name of the corresponding volume. As a given volume may describe several similar detectors in the physical setup, some additional information is needed for associating correctly the hits with the physical detectors.

When using `GSDET` the user has to enter the (shortest) list of volume **names** (the vector `CHNMSV`), which permits unambiguous identification of the path through the physical tree, even in the presence of multiple copies. This identification is obtained by specifying a list of volume **numbers** (the vector `NUMBV`), in a one to one correspondence with the list of volume names. This list, after packing, will constitute the identifier of the physical detector.

If `GSDETV` is used instead of `GSDET` then the routine `GGDETV` (called by `GGCLOS`) constructs the lists `CHNMSV` automatically and stores them in the structure `JSET`.

3 The user tools

The data structure `JSET` is built through calls to the routine `GSDET` or `GSDETV` which assign detectors to sets and define their parameters. After this, the following routines can be called, for each detector, to complete the structure:

`GSDETH`   provides the parameters required for the storage of the hit elements in the data structure `JHITS`, such as the packing and scaling conventions;

`GSDETD`   provides the parameters required for the storage of the digitisations in the structure `JDIGI`, such as the packing conventions;

`GSDETU`   adds the user parameters, which may consist, for instance, of the intrinsic detector characteristics needed for computing the digitisations.

To permit storage of more than one type of hit for a given sensitive detector, or to provide additional detector entries, detector *aliases* can be defined through calls to the routine `GSDETA`. They are entered in the `JSET` structure as new detectors, with the same geometrical characteristics as the original one. The user has the possibility to call appropriate routines `GSDETH`, `GSDETD` and `GSDETU` for this new detector.

During the tracking, for each step inside the sensitive detectors, under control of the subroutine `GUSTEP`, the hits can be stored in the data structure `JHITS` through the subroutine `GSAHIT` (or `GSCHIT`, more appropriate for calorimetry). For each hit the information consists of:

- the reference to the track in the structure `JKINE`;

- the packed identifier of the physical detector;

- the packed data for the different elements of the hit.

When the tracking has been completed for the whole event the digitisations can be computed in the user subroutine `GUDIGI` which may extract the hits with the subroutine `GFHITS` and store the digitisations in the data structure `JDIGI`, with the subroutine `GSDIGI`. For each digitisation the information should at least consist of:

- the reference to the track(s);

- the packed identifier of the physical detector;

- the packed data for the digitisation itself.

4 Retrieval of geometrical information

The packed identifier of a physical detector, stored as part of the hit (or digitisation) information, is returned unpacked by the routine `GFHITS` (or `GFDIGI`) which extracts the information from the `JHITS` or `JDIGI` structures, and may be used to retrieve the geometrical characteristics of the given detector.

If the detectors have been defined by the routine `GSDETV`, the geometrical information can be retrieved by the routines `GFPATH` and `GLVOLU`. `GFPATH` prepares the lists `CHNAM` and `LNUM` required by `GLVOLU` (`[GEOM001]`), from the information preprocessed at initialisation time by the routine `GGDETV` and stored in the structure `JSET`

Sensitive `DET`ector definition

```
    CALL GSDET  (CHSET,CHDET,NV,CHNMSV,NBITSV,IDTYP,NWHI,NWDI,ISET*,IDET*)
```

CHSET   (`CHARACTER*4`) set identifier, user defined;
CHDET   (`CHARACTER*4`) detector identifier, has to be the name of an existing volume;
NV   (`INTEGER`) number of volume descriptors;
CHNMSV   (`CHARACTER*4`) array of `NV` volume descriptors;
NBITSV   (`INTEGER`) array of `NV`, `NBITSV(I)` (`I=1,...,NV`) is the number of bits in which to pack the copy number of volume `CHNMSV(I)`;
IDTYP   (`INTEGER`) detector type, user defined;
NWHI   (`INTEGER`) initial size of `HITS` banks;
NWDI   (`INTEGER`) initial size of `DIGI` banks;
ISET   (`INTEGER`) position of set in bank `JSET`;
IDET   (`INTEGER`) position of detector in bank `JS=LQ(JSET-ISET)`.

Assigns detector `CHDET` to the set `CHSET` and defines its basic parameters.

Note: The vector `CHNMSV` (length `NV`) contains the list of volume names which permit unambiguous identification of all copies of volume `CHDET` [see example in [`HITS110`]. Each element of the vector `NBITSV` (length `NV`) is the number of bits used for packing the number of the corresponding volume, when building the packed identifier of a given physical detector.

For more details see the example given in [`HITS110`]. The detector type `IDTYP` is not used internally by `GEANT` and can be used to distinguish quickly between various kinds of detectors, in the routine `GUSTEP` for example.

```
    CALL GSDETV  (CHSET,CHDET,IDTYP,NWHI,NWDI,ISET*,IDET*)
```

The arguments of this routine are the same than the previous one, but `NAMES, NBITSV` will be computed by `GGDETV` called by `GGCLOS`) (see [`HITS001`]).

```
    CALL GFDET  (CHSET,CHDET,NV*,CHNMSV*,NBITSV*,IDTYP*,NWHI*,NWDI*,ISET*,IDET*)
```

Returns the parameters for detector `CHDET` of set `CHSET`, the arguments have the same meaning than for routine `GSDET`.

```
    CALL GPSETS  (CHSET,CHDET)
```

Prints `SET` and `DET`ector parameters.

CHSET   (`CHARACTER*4`) set to be printed, if `*` prints all detectors of all sets;
CHDET   (`CHARACTER*4`) detector to be printed, if `*` prints all detectors of set `CHSET`.

Detector aliases

Detector `aliases` can be specified for any sensitive detector for which the user either needs to store more than one type of hit or wants to define additional detector entries.

```
CALL GSDETA  (CHSET,CHDET,CHALI,NWHI,NWDI,IALI*)
```

CHSET   (`CHARACTER*4`) set name;
CHDET   (`CHARACTER*4`) name of the detector for which an alias is being defined;
CHALI   (`CHARACTER*4`) alias name;
NWHI   (`INTEGER`) initial number of words of `HITS` banks;
NWDI   (`INTEGER`) initial number of words of `DIGI` banks;
IALI   (`INTEGER`) position of alias in bank `JS=LQ(JSET-ISET)`.

Defines an alias `CHALI` for detector `CHDET` of set `CHSET` and enters it in the `JSET` structure as an additional detector in the corresponding set, at the position `IALI`. The new detector will be a copy at position `IALI` of the original detector `CHDET`, with empty links to the `GSDETH`, `GSDETD` and `GSDETU` parameter banks. The user can therefore call these three routines again with the arguments appropriate to the detector `CHALI`. Several aliases can be defined for the same detector through calls to `GSDETA`.

DETector hit parameters

CALL **GSDETH** (CHSET,CHDET,NH,CHNAMH,NBITSH,ORIG,FACT)

CHSET   (CHARACTER*4) set name;

CHDET   (CHARACTER*4) detector name;

NH   (INTEGER) number of the components of a hit;

CHNAMH   (CHARACTER*4) array of NH names for the hit components;

NBITSH   (INTEGER) array of NH, NBITSH(I) (I=1,...NH) is the number of bits in which to pack the Ith component of the hit;

ORIG   (REAL) array of NH offset applied before packing the hits values;

FACT   (REAL) array of NH scale factors applied before packing the hits values;

Defines hit parameters for detector CHDET of set CHSET. The routine must be called at initialisation time once the geometrical volumes have been defined to describe the hit elements and the way to pack them in the data structure JHITS. The value of the hit before packing is transformed in the following way:

$$\texttt{VAL(I) = (HIT(I)+ORIG(I))} \times \texttt{FACT(I)}$$

Example

Assume an electromagnetic calorimeter ECAL divided into 40 PHI sections called EPHI. Each EPHI division is in turn divided along the z axis in 60 sections called EZRI. Each EZRI is finally divided into 4 lead glass blocks called BLOC. The geometrical information to describe one hit will then be:

- the EPHI section number (between 1 and 40);

- the EZRI division number (between 1 and 60);

- the BLOC number (1 to 4).

The quantities which should be stored for each hit are:

X x position of the hit in the lead glass block ($-1000 < x < 1000$);

Y y position of the hit in the lead glass block ($-1000 < y < 1000$);

Z z position of the hit in the lead glass block ($-1000 < z < 1000$);

E   energy of the particle;

ELOS   the energy deposited;

In this scheme a hit could look like:

Element	Value
EPHI	12
EZRI	41
BLOC	3
X	7.89 cm
Y	-345.6 cm
Z	1234.8 cm
E	12 Gev
ELOS	11.85 Gev

The code to define the SET/DET/HIT information could be:

```
      CHARACTER*4 CHNMSV(3),CHNAMH(5)
      DIMENSION   NBITSV(3),NBITSH(5)
      DIMENSION   ORIG(5),FACT(5)
*---
      DATA CHNMSV/'EPHI','EZRI','BLOC'/
      DATA NBITSV/    6,    6,    3/
*---
      DATA CHNAMH /'X  ','Y  ','Z  ','E  ','ELOS'/
      DATA NBITSH /   16,   16,   16,   16,   16/
      DATA ORIG   / 1000., 1000., 1000.,   0.,   0./
      DATA FACT   /   10.,   10.,   10.,  100.,  100./
*---
      CALL GSDET ('ECAL','BLOC',3,CHNMSV,NBITSV,2,100,100,ISET,IDET)
      CALL GSDETH('ECAL','BLOC',5,CHNAMH,NBITSH,ORIG,FACT)
```

> CALL **GFDETH** (CHSET,CHDET,NH*,CHNAMH*,NBITSH*,ORIG*,FACT*)

Returns the hit parameters for detector CHDET of set CHSET. All arguments are as explained above.

DETector Digitisation parameters

```
CALL GSDETD  (CHSET,CHDET,ND,CHNMSD,NBITSD)
```

CHSET   (CHARACTER*4) set name;

CHDET   (CHARACTER*4) detector name;

ND   (INTEGER) number of elements per digitisation;

CHNMSD   (CHARACTER*4) array of ND names for the digitisation elements;

NBITSD   (INTEGER) array of ND, NBITSD(I) (I=1,...,ND) is the number of bits into which to pack the Ith element of the digit.

Defines digitisation parameters for detector CHDET of set CHSET. The routine must be called at initialisation, after the geometrical volumes have been defined, to describe the digitisation elements and the way to pack them in the data structure JDIGI.

Example

Following on from the example in [HITS110], we want to add the digitisation information to detector EPHI of set ECAL. The information which should be stored for each digitisation is the ADC pulse height in the lead glass block, so that a digitisation in this scheme could look like:

Element	Value
EPHI	12
EZRI	41
BLOC	3
ADC	789

The code to define the digitisation information could be:

```
CHARACTER*4 CHNMSD
DATA CHNMSD/'ADC '/
DATA NBITSD/16/

CALL GSDETD('ECAL','BLOC',1,CHNMSD,NBITSD)
```

```
CALL GFDETD  (CHSET,CHDET,ND*,CHNMSD*,NBITSD*)
```

Returns the digitisation parameters for detector CHDET of set CHSET. All arguments as explained in GSDETD.

User detector parameters

```
    CALL GSDETU  (CHSET,CHDET,NUPAR,UPAR)
```

CHSET   (CHARACTER*4) set name;
CHDET   (CHARACTER*4) detector name;
NUPAR   (INTEGER) number of parameters;
UPAR   (REAL) array of NUPAR parameters.

Stores user parameters for detector CHDET of set CHSET. The routine must be called at initialisation after the geometry has been defined.

```
    CALL GFDETU  (CHSET,CHDET,NUPAR,NW*,UPAR*)
```

The parameters have the same meaning than in the previous routine, apart from:

NUPAR   (INTEGER) size of the UPAR array;
NW   (INTEGER) number of parameters returned in UPAR, $NW \leq NUPAR$;

Returns the user parameters for detector CHDET of set CHSET.

The SET data structure JSET
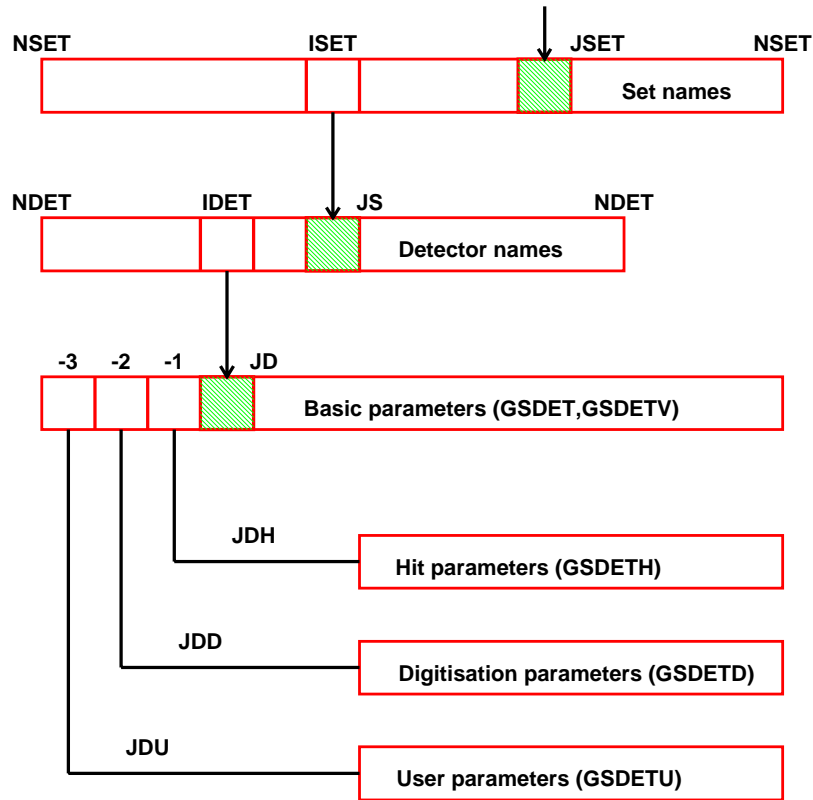

Figure 31: Example of geometrical tree structure

JS = LQ(JSET-ISET) pointer to detector set number ISET The JSET data structure is filled by GSDET, GSDETV, GSDETH, GSDETD, GSDETU and possibly by GSDETA.

Routines to store and retrieve `HITS`

```
    CALL GSAHIT  (ISET,IDET,ITRA,NUMBV,HITS,IHIT*)
```

ISET   (`INTEGER`) set number (see below);
IDET   (`INTEGER`) detector number;
ITRA   (`INTEGER`) number of the track producing this hit
NUMBV   (`INTEGER`) array of volume numbers corresponding to list `NAMESV` of `GSDET`;
HITS   (`REAL`) array of values for current hit elements;
IHIT   (`INTEGER`) current hit number, if 0 the hit has not been stored.

Stores element values for current hit into the data structure `JHITS`. The values `ISET`, `IDET` and `NUMBV` can be found in the corresponding variables of common `/GCSETS/`. These values are set by the routine `GFINDS` every time that a particle is in a defined detector.

```
    CALL GSCHIT  (ISET,IDET,ITRA,NUMBV,HITS,NHSUM,IHIT*)
```

Same action as `GSAHIT`, but in case the detector identified by `ISET`, `IDET` and `NUMBV` contains already a hit for the same track, the routine will make a cummulative sum for the latest `NHSUM` elements of `JHITS`. The other previous elements of `JHITS` are replaced. That facility is particularly interesting in the case of hits generated into a calorimeter. No packing (i.e. 32 bits per hit element) should be requested for the last `NHSUM` hits in `GSDETH` and for these hits `ORIG` should be set to 0.

```
    CALL GPHITS  (CHSET,CHDET)
```

CHSET   (`CHARACTER*4`) set name, if `'*'` prints all `JHITS` banks of all sets;
CHDET   (`CHARACTER*4`) detector name, if `'*'` prints hits in all detectors of set `CHSET`.

Prints `JHITS` banks for detector `CHDET` of set `CHSET`.

```
    CALL GFHITS  (CHSET,CHDET,NVDIM,NHDIM,NHMAX,ITRS,NUMVS,
                  ITRA*,NUMBV*,HITS*,NHITS*)
```

CHSET   (`CHARACTER*4`) set name;
CHDET   (`CHARACTER*4`) detector name;
NVDIM   (`INTEGER`) 1st dimension of arrays `NUMBV` and `NUMVS`: $1 \leq NVDIM \leq NV$ argument of `GSDET`;
NHDIM   (`INTEGER`) 1st dimension of array `HITS`: $1 \leq NHDIM \leq NH$ argument of `GSDETH`;
NHMAX   (`INTEGER`) maximum number of hits to be returned, this should be not larger than the second dimension of array `NUMBV` and `HITS`;
ITRS   (`INTEGER`) number of the selected track, if `ITRS=0`, all tracks are taken;
NUMVS   (`INTEGER`) is a 1-dimension array of `NVDIM` elements that contains the list of volume numbers which identify the selected detector, 0 is interpreted as 'all valid numbers';
ITRA   (`INTEGER`) is a 1-dim array of dimension `NHMAX` that contains on output for each hit the number of the track which has produced it;
NUMBV   (`INTEGER`) 2-dim array (`NVDIM`,`NHMAX`) that containis on output for each hit the list of volume numbers which identify the detector, all values set to 0 means that no more volumes are stored;
HITS   (`REAL`) 2-dim array (`NHDIM`,`NHMAX`) that containis `NHITS` hits;

NHITS   (INTEGER) number of hits returned, in case the total number of hits is greater than NHMAX, NHITS is set to NHMAX+1 and NHMAX hits are returned.

This rotine returns the hits produced by track ITRS (or by any track) in the detector CHDET identified by the list NUMVS belonging to set CHSET.

HITS(1,I)   is element 1 of hit number I;
NUMBV(1,I)   is volume number 1 of hit number I;
ITRA(I)   is the track number corresponding to hit number I;

The arrays NUMVS, NUMBV, HITS and ITRA must be dimensioned to:

    NUMVS(NVDIM)
    NUMBV(NVDIM,NHMAX)
    HITS(NHDIM,NHMAX)
    ITRA(NHMAX)

    CALL **GFPATH** (ISET,IDET,NUMBV,NLEV*,LNAM*,LNUM*)

ISET   (INTEGER) set number;
IDET   (INTEGER) detector number;
NUMBV   (INTEGER) array of numbers which identify uniquely detector number IDET;
NLEV   (INTEGER) number of elements filled of arrays LNAM and LNUM;
LNAM   (INTEGER) array of NLEV volume names stored in ASCII code in integers;
LNUM   (INTEGER) array of NLEV copy numbers.

This routine returns the list of volume names and numbers which identify the complete ancestry in the JVOLUM data structure of the volume corresponding to the detector number IDET in set number ISET and which is identified by the volume numbers NUMBV (see GFHITS).

GFPATH assumes that the detectors have been declared via GSDETV and not GSDET. The main use of GFPATH is to prepare the lists LNAM and LNUM required by the routine GLVOLU to fill the common /GCVOLU/. Once /GCVOLU/ is properly filled, it is possible to use the GEANT routines to transform from the local to the master reference system and so on.

JHITS **data structure**
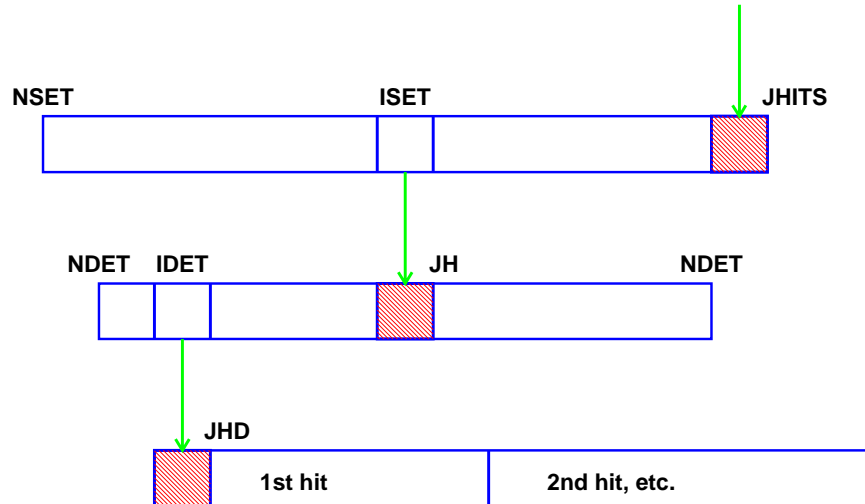

Figure 32: Layout of the JHITS data structure

`JH=LQ(JHITS-ISET)`	pointer to hits structure for set number ISET
`IQ(JH+IDET)`	number of words used for storing the hits of detector number IDET
`JHD=LQ(JH-IDET)`	pointer to hits bank for detector number IDET of set number ISET
`IQ(JHD+1)`	1st word of 1st hit
`IQ(JHD+NWH+1)`	1st word of 2nd hit
`JS=LQ(JSET-ISET)`	pointer to the structure containing the description of set number ISET
`JD=LQ(JS-IDET)`	pointer to the bank containing the description of detector number IDET of set number ISET
`NWH=IQ(JD+3)`	number of words in which a hit of detector number IDET of set number ISET is stored

The JHITS structure is filled with the routines GSAHIT and GSCHIT. The routine GFHITS can be used to get the hits for a detector IDET in set ISET.

Routines to store and retrieve `DIGI`tisations

```
    CALL GSDIGI  (ISET,IDET,LTRA,NTRA,NUMBV,KDIGI,IDIG*)
```

ISET   (INTEGER) set number;
IDET   (INTEGER) detector number;
LTRA   (INTEGER) array of NTRA track numbers producing this digitisation;
NUMBV   (INTEGER) volume numbers corresponding to list NAMESV of GSDET;
KDIGI   (INTEGER) array of current digisation elements;
IDIG   (INTEGER) stored digitisation number, if 0, digitisation has not been stored.

Stores element values for current digitisation into the data structure JDIGI.

```
    CALL GPDIGI  (CHSET,CHDET)
```

CHSET   (CHARACTER*4) set name, if '*' prints all JDIGI banks of all sets;
CHDET   (CHARACTER*4) detector name, if '*' prints digitisations in all detectors of set; CHSET

Prints JDIGI banks for detector CHDET of set CHSET.

```
    CALL GFDIGI  (CHSET,CHDET,NTDIM,NVDIM,NDDIM,NDMAX,NUMVS,
                  LTRA*,NTRA*,NUMBV*,KDIGI*,NDIGI*)
```

CHSET   (INTEGER) set name;
CHDET   (INTEGER) detector name;
NTDIM   (INTEGER) 1st dimension of LTRA, maxmum number of tracks contributing to each hit to be returned;
NVDIM   (INTEGER) 1st dimension of arrays NUMVS, NUMBV, same as argument NV of GSDET;
NDDIM   (INTEGER) 1st dimension of KDIGI, same as argument ND of GSDETD;
NDMAX   (INTEGER) maximum number of digitisations to be returned, second dimension of arrays NTDIM, NUMBV and KDIGI;
NUMVS   (INTEGER) is a 1-dim array of length NVDIM that contains the copy numbers identifying the detector to be selected, all 0 is interpreted as all copies of detector CHDET;
LTRA   (INTEGER) is a 2-dim array NTDIM,NDMAX that contains for each digitisation the numbers of the tracks which have produced it;
NTRA   (INTEGER) is a 1-dim array of length NDMAX that contains, for each digitisation, the number of tracks contributing, in case this number is greater than NTDIM, only the first NTDIM corresponding tracks are returned on LTRA;
NUMBV   (INTEGER) is a 2-dim array NVDIM,NDMAX that contains, for each digitisation, the list of volume numbers which identify each detector;
KDIGI   (INTEGER) is a 2-Dim array NDDIM,NDMAX that contains the NDIGI digitisations returned;
NDIGI   (INTEGER) is the total number of digitisations in this detector, in case the total number of digitisations is greater than NDMAX, NDIGI is set to NDMAX+1 and only NDMAX digitisations are returned.

Returns the digitisations for the detector CHDET identified by the list of copy numbers NUMVS belonging to set CHSET. The maning of the variables is the following:

```
KDIGI(1,I)    digitisation element 1 for digitisation number I
NUMBV(1,I)    first volume number for digitisation number I
LTRA (1,I)    number of the first track contributing to digitisation number I
```
In the calling routine, the arrays LTRA, NTRA, NUMVS, NUMBV, KDIGI must be dimensioned to:

```
LTRA (NTDIM,NDMAX)
NTRA (NDMAX)
NUMVS(NVDIM)
NUMBV(NVDIM,NDMAX)
KDIGI(NDDIM,NDMAX)
```

The `JDIGI` data structure
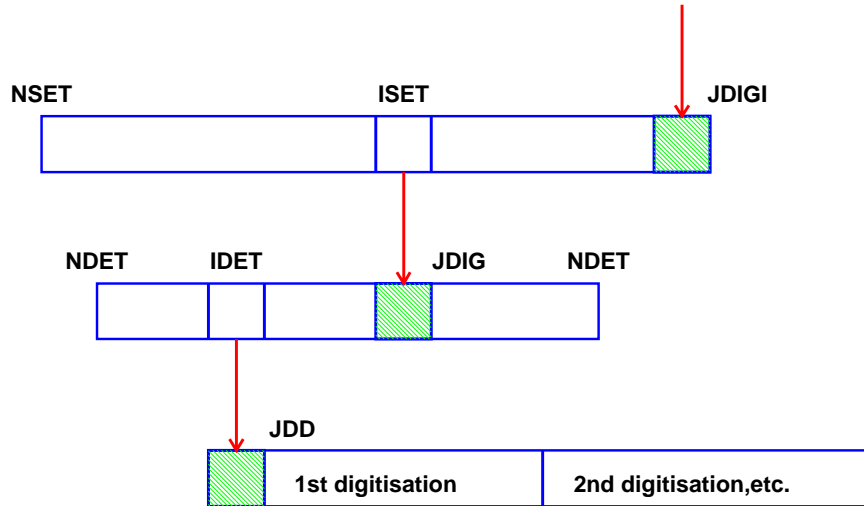

Figure 33: Layout of the `JDIGI` data structure

`JDIG=LQ(JDIGI-ISET)`	pointer to digitisations structure for set number `ISET`
`JDD=LQ(JDIG-IDET)`	pointer to digitisations of detector number `IDET` of set number `ISET`
`IQ(JDIG+IDET)`	pointer to last word of last digitisation for detector number `IDET`
`IQ(JDD+1)`	1st word of 1st digitisation
`IQ(JDD+N+1)`	1st word of 2nd digitisation
`JS=LQ(JSET-ISET)`	pointer to the structure containing the description of digitisations of set number `ISET`
`JD=LQ(JS-IDET)`	pointer to the structure containing the description of digitisations of detector number `IDET`
`NWD=IQ(JD+5)`	number of elements of digitisation of set/detector `ISET/IDET`
`NTRA`	number of tracks contributing to digitisation
`N=NWD+NTRA/2+1`	N varies from digitisation to digitisation

The `JDIGI` structure is filled with the routine `GSDIGI`. The routine `GFDIGI` can be used to get the digitisations for a detector `IDET` in set `ISET`.

Intersection of a track with a cylinder or a plane

```
CALL GICYL  (R,X1,X2,S1,S2,IC,XINT*,SINT*,PZINT*,IFLAG*)
```

R   (REAL) radius of cylinder in cm;

X1   (REAL) array of 6, $(x, y, z, dx/ds, dy/ds, dz/ds)$ of 1st point;

X2   (REAL) array of 6, $(x, y, z, dx/ds, dy/ds, dz/ds)$ of 2nd point;

S1   (REAL) track length s at 1st point;

S2   (REAL) track length s at 2nd point;

IC   (INTEGER) type of interpolation:

           1   straight line defined as `(Xi(1),Xi(2),Xi(3))` + s `(Xi(4),Xi(5),Xi(6))`, where `i` is 1 or 2 according to which of the two points is *inside* the cylinder;

           2   straight line going from `(X1(1),X1(2),X1(3))` to `(X2(1),X2(2),X2(3))`;

           3   third degree curve with:

$$\vec{P}(s) = \vec{a}\, s^3 + \vec{b}\, s^2 + \vec{c}\, s + \vec{d} \qquad \mathrm{X}i = \left(\vec{P}(\mathrm{S}i),\ \left.\frac{d\vec{P}}{ds}\right|_{s=\mathrm{S}i} \right) \quad i = 1, 2$$

XINT   (REAL) array of 6 x, y, z, dx/ds, dy/ds, dz/ds at intersection point;

SINT   (REAL) S at intersection point;

PZINT   (REAL) ϕ, z, $d\phi/dr$, dz/dr in cylindrical coordinates at intersection point;

IFLAG   (INTEGER) return flag:

           0   track does not intersect cylinder;

           1   track intersects cylinder.

Calculates intersection of track with a cylinder of radius R. The track is approximated by a cubic in the track length. To improve stability, the coordinate system is shifted.

```
CALL GIPLAN  (YC,X1,X2,S1,S2,IC,XINT*,SINT*,PZINT*,IFLAG*)
```

The arguments have the same meaning than in the previous routine, apart from:

YC   (REAL) y coordinate of plane;

Calculates intersection of track with a plane parallel to $x - z$. The track is approximated by a cubic in the track length. To improve stability, the coordinate system is shifted.

Note: the default accuracy is 10 microns. The value of EPSI (internal variable) must be changed for a better precision.

Digitisation for drift- or MWP- Chambers

    CALL **GPDRIF**   (DETREP,HITREP,IOUT*)

DETREP   (REAL) array of 6 with detector description:

      1   number of wires;

      2   wire spacing in cm;

      3      $\sin(\alpha)$;

      4      $\cos(\alpha)$;

      5   distance of wire 1 from the origin in cm;

      6   drift velocity (cm/nsec)

HITREP   (REAL) array of 2 with track description:

      1   x coordinate of intersection;

      2   y coordinate of intersection;

IOUT   (INTEGER) result of digitisation:

      1   wire number;

      2   drift time (signed to avoid left/right ambiguity).

Digitisation routine for a plane drift chamber. The drift chamber is supposed to be in the $x - y$ plane. The normal to the wires in the $x - y$ plane and the z axis form an angle α.

    CALL **GCMWPC**   (DETREP,HITREP,IOUT*)

DETREP   (REAL) array of 6 with detector description:

      1   number of wires;

      2   wire spacing (radians);

      3      $d\theta/dz$ along the wires;

      4   θ of a point on wire 1;

      5   z of a point on wire 1 corresponding to θ=DETREP(4);

      6   gap width;

HITREP   (REAL) array of 4 with track description:

      1   θ coordinate of intersection;

      2   z coordinate;

      3      $d\theta/dr$;

      4   dz/dr;

IOUT   (INTEGER) array of 4 with result of digitisation:

      1   wire number (-1 if missing);

      2   cluster size;

      3   wire number of second cluster if any;

      4   cluster size;

Routine to compute one or two digitisations produced by a hit on a cylindrical MWPC. The chamber is a cylinder of thickness DETREP(6) which should be small compared with the radius.

    CALL **GPMWPC**   (DETREP,HITREP,IOUT*)

DETREP   (REAL) array of 6 with detector description:

      1   number of wires;

      2   wire spacing (radians);

      3      $\sin(\alpha)$;

      4      $\cos(\alpha)$;

      5   distance of wire 1 from the origin in cm;

      6   gap width;

HITREP   (REAL) array of 4 with track description:

      1   x coordinate of intersection;

      2   y coordinate of intersection;

      3   dx/dz;

      4   dy/dz;

IOUT   (INTEGER) array of 2 with result of digitisation:

      1   wire number (-1 if missing);

      2   cluster size;

Digitisation routine for a plane MWPC.

Digitisation for drift chambers

```
CALL GCDRIF   (RADD,ZMIN,ZMAX,DETREP,HITREP,IOUT*)
```

RADD   (`REAL`) radius of cylindrical chamber in cm;

ZMIN   (`REAL`) z of lower end of cylindrical chamber;

ZMAX   (`REAL`) z of upper end of cylindrical chamber;

DETREP   (`REAL`) array of 8 with detector description:

     1   number of wires;

     2   wire spacing in ϕ (radians);

     3   cosine of wire angle with respect to the z axis;

     4   sine of wire angle with respect to the z axis (signed like $d\phi/dz$);

     5      $d\phi/dz$ along wire;

     6   ϕ of point with $z = 0$ on wire 1;

     7   drift velocity (cm nsec^{-1});

     8   if > 0 user routine `GUDTIM` will be called to calculate drift time;

HITREP   (`REAL`) array of 4 describing the track:

     1   ϕ coordinate of intersection;

     2   z coordinate of intersection;

     3      $d\phi/dr$;

     4   dz/dr;

IOUT   (`INTEGER`) array of 4 with digitisation information:

     1   wire number (1...`NWI` with increasing phi), -1 if `DETREP` parameters are inconsistent;

     2   drift time in nsec, > 0 if $\phi(hit) > \phi(wire)$;

     3   digitised current division information (relative position of charge along wire, per mille);

     4   amount of charge deposited onto wire.

Digitisation routine for a cylindrical drift chamber.

```
                     Charge
      .                |                      .
      |                .                      |
      ======================================= SENSE WIRE
   ...............................................> Z (cm)
      Z                Z                      Z
       l                                       u
   ...............................................> ICD (0<ICD<1000)
      O                ICD                    1000
          ICD                  (1000-ICD)
```
Figure 34: Coordinate system along the wire

Knowing the position Z of the deposit of charge we can calculate

$$\mathtt{ICD} = L\frac{Z - Z_l}{Z_u - Z_l}$$

where $L = 1000$ in the program. This is the information stored into `IOUT(3)`.

CALL **GCDERR** (ICD*,ERP,ERS)

ICD (`INTEGER`) digitised current division information ($\leq$ `ICD` ≤ 1000), overwritten on output with the modified value taking into account the errors;

ERP (`REAL`) variance of Gaussian pedestal errors on the measured pulse heights relative to the sum of the pulse heights;

ERS (`REAL`) variance of Gaussian slope errors on the measured pulse heights relative to the each pulse heights.

Routine to calculate the error on the current division information as obtained by `GCDRIF`. Here we assume that `ICD` has been determined by measuring the pulse heights I_1, I_2 at the two ends of the wire with the formula:

$$\mathtt{ICD} = L\,\frac{I_2}{I_+} \qquad \text{with} \qquad I_+ = I_1 + I_2$$

Its error is determined by:

$$\delta\mathtt{ICD} = -\frac{\mathtt{ICD}}{I_+}\delta I_1 + \frac{L - \mathtt{ICD}}{I_+}\delta I_2 \quad \text{and} \quad \delta I_1 = \delta_1 + \epsilon_1\,I_1 \;\; ; \;\; \delta I_2 = \delta_2 + \epsilon_2\,I_2$$

δ_1 and δ_2 are of dimension [I] and represent the *pedestal* errors. ϵ_1 and ϵ_2 are the *slope* errors. Errors are independent (no correlations), with a Gaussian distribution with average 0 and `ERP` as relative variance for pedestals δ_i/I_+ and `ERS` as variance for slopes ϵ_i. This gives the final result

$$\delta\mathtt{ICD} = \underbrace{-\frac{\delta_1}{I_+}\mathtt{ICD} + \frac{\delta_2}{I_+}(L - \mathtt{ICD})}_{pedestals} + \underbrace{(\epsilon_2 - \epsilon_1)\frac{\mathtt{ICD}(L - \mathtt{ICD})}{L}}_{slope}$$

`GCDERR` sets the `ICD` obtained from `GCDRIF` to `ICD` = `ICD` + δ`ICD` with $0 \leq$ `ICD` $\leq L$.

VALUE = **GUDTIM** (DETREP,HITREP,IW1,DIS)

The arguments have the same meaning than for `GCDRIF` apart from:

IW1 (`INTEGER`) wire number which will generate a signal;

DIS (`REAL`) distance from the track to the wire;

This function has to be written by the user to return the drift time in nanoseconds.

HITS Bibliography

The I/O routines

The I/O routines allow one to read, write or print the `GEANT` data structures. All `GEANT` I/O is handled though the `ZEBRA` system, which provides the following facilities:

- native and machine independent I/O to and from disk and tape devices;

- sequential and direct access I/O (from disk);

This allows, for example, to generate events on one machine, dump the data structures to a mass storage device, and then read them back for further processing on a different machine.

This section describes the various routines for I/O in `GEANT`. For a complete reference on the `ZEBRA` I/O system the user is referred to the `ZEBRA` documentation [1, 8].

ZEBRA sequential files handling

CALL **GOPEN** (LUN,CHOPT,LEN,IER*)

LUN   (INTEGER) logical unit number, $1 \leq \mathrm{LUN} < 100$;
CHOPT   (CHARACTER*(*)) any valid combination of FZFILE options (see [1, 8]), the most common being:

      I   input file;
      O   output file;
      X   exchange mode file;

LEN   (INTEGER) maximum record length, for more details see routine FZFILE in the ZEBRA manual;
IER   (INTEGER) error flag:

      0   legal open request;
      1   attempt to open more than 5 ZEBRA sequential files;

Opens a ZEBRA FZ file for sequential I/O of GEANT data structures. No more than 5 files can be open at any one time.

CALL **GCLOSE** (LUN,IER*)

LUN   (INTEGER) logical unit to be closed, if 0 all ZEBRA FZ streams will be closed;
IER   (INTEGER) error flag:

      0   legal close request;
      1   no unit was found open;

This routine closes one or all ZEBRA FZ file(s). This is a mandatory routines for all open ZEBRA files before the end of the program. Failure to call this routine may cause files to be incompletely written to the storage media.

Data structure I/O with sequential files

```
   CALL GFIN  (LUN,CHOBJ,NKEYS,IDVERS*,CHOPT,IER*)
```

LUN   (`INTEGER`) logical unit;
CHOBJ   (`CHARACTER*4`) array with the data structures to be read:

        MATE   material;
        TMED   tracking medium;
        VOLU   volumes;
        ROTM   rotation matrix;
        SETS   detector set;
        PART   particle;
        SCAN   scan geometry;
        DRAW   drawing;
        INIT   all of the above;
        KINE   this keyword will trigger the read of `KINE` and `VERT` unless the flag `S` is set;
        DIGI   digitisation;
        HEAD   event header;
        HITS   hits;
        RUNG   run;
        STAK   particle temporary stack;
        STAT   volume statistic;
        VERT   vertex;
        JXYZ   track points;
        TRIG   this keyword will trigger the read of `DIGI`, `HEAD`, `HITS`, `KINE`, `VERT` and `JXYZ` unless the `S` flag is set;

NKEYS   (`INTEGER`) number of keys in array `CHOBJ`;
IDVERS   (`INTEGER`) version of the data structure to be read in, if 0 it will read any version, on output it contains the version of the data structure read in;
CHOPT   (`CHARACTER*(*)`) option:

        I   among the data structures specified in `CHOBJ` read only the initialisation ones;
        K   among the data structures specified in `CHOBJ` read only `KINE` and `TRIG`, if present;
        T   among the data structures specified in `CHOBJ` read only `DIGI`, `HEAD`, `HITS`, `KINE`, `VERT` and `JXYZ`, if present;
        S   interpret `KINE` to mean only the `KINE` data structure and ignore `TRIG` and `INIT`;
        Q   quiet option, no message is printed;

IER   (`INTEGER`) error flag:

        <0   ZEBRA error flag as returned in `IQUEST(1)`;
         0   read completed successfully;
        >0   if only `IER`] structures read in out of the `NKEYS` requested;

Routine to read `GEANT` object(s) from a `ZEBRA`/`FZ` file. The data structures from disk are read in memory. The `FZ` data base must have been been created via `GOPEN`/`GFOUT`. Example:

```
CALL GOPEN(1,'I',1024,IER)
IDVOLU = O
IDMATE = O
IDTMED = O
IDROTM = O
IDPART = O
IDSCAN = O
IDSETS = O
CALL GFIN (1,'VOLU',1,IDVOLU,' ',IER)
CALL GFIN (1,'MATE',1,IDMATE,' ',IER)
CALL GFIN (1,'TMED',1,IDTMED,' ',IER)
CALL GFIN (1,'ROTM',1,IDROTM,' ',IER)
CALL GFIN (1,'PART',1,IDPART,' ',IER)
CALL GFIN (1,'SCAN',1,IDSCAN,' ',IER)
CALL GFIN (1,'SETS',1,IDSETS,' ',IER)
```

CALL **GFOUT** (LUN,CHOBJ,NKEYS,IDVERS,CHOPT,IER*)

The arguments have the same meaning than for GFIN with the following differences:

IDVERS   (INTEGER) version identifier of the data structures to be written out;

Routine to write GEANT object(s) into a ZEBRA/FZ file. The data structures from memory are written on the file. The FZ data base must have been been created via GOPEN/GFOUT. Example:

```
CALL GOPEN(1,'O',1024,IER)
CALL GFOUT (1,'VOLU',1,IDVOLU,' ',IER)
CALL GFOUT (1,'MATE',1,IDMATE,' ',IER)
CALL GFOUT (1,'TMED',1,IDTMED,' ',IER)
CALL GFOUT (1,'ROTM',1,IDROTM,' ',IER)
CALL GFOUT (1,'PART',1,IDPART,' ',IER)
CALL GFOUT (1,'SCAN',1,IDSCAN,' ',IER)
CALL GFOUT (1,'SETS',1,IDSETS,' ',IER)
```

Note: the routines GGET and GSAVE are obsolete and should not be used.

ZEBRA **direct access files handling**

I/O with direct access files is the most efficient way to use direct access devices. All the routines described in this section and in (`[IOPA500]`) are based on the `ZEBRA-RZ` package and the user is referred to the related documentation [8] for an understanding of the basic principles.

```
    CALL GRFILE  (LUN,CHFILE,CHOPT)
```

LUN   (`INTEGER`) logical unit number;
CHFILE   (`CHARACTER*(*)`) file name;
CHOPT   (`CHARACTER*(*)`) any valid option for `RZOPEN`, `RZMAKE` and `RZFILE` and in particular:

    N   create a new file;
    U   open an existing file for update;
    Q   the initial allocation (default 1000 records) is in `IQUEST(10)`;
    I   read all initialisation data structures (see description of `GRIN/GROUT`) from file to memory;
    O   write all initialisation data structures from memory to file;

This routine opens a file for direct access I/O of `ZEBRA` data structures. By default the file is opened in exchange mode and the option `W` is added, which creates an `RZ` top level directory with the name `//LUNnn` where `nn` is the logical unit number.

The default allocation of an `RZ` directory is enough for 1000 records, which allows for a 4Mb file with the standard record length of 1024 words. If a larger file is needed, the size of the directory should be changed when creating the file. This can be done by assigning to the variable `IQUEST(10)` in the common `/QUEST/` the requested number of records, and calling `GRFILE` with the option `Q` as shown in the following example:

```
      COMMON / QUEST / IQUEST(100)
      .
      .
      .
      IQUEST(10) = 5000
      CALL GRFILE(1,'mygeom.geom','Q')
```

```
    CALL GRMDIR  (CHDIR,CHOPT)
```

CHDIR   (`CHARACTER*(*)`) subdirectory name to create;
CHOPT   option string:

    ' '   create a subdirectory;
    S   create a subdirectory and set the current directory to it;

This routine creates an `RZ` subdirectory.

```
    CALL GREND  (LUN)
```

LUN   (`INTEGER`) logical unit number (see `RZEND` in the `ZEBRA` manual [8]);

Routine to close an `RZ` file. It is very important to call this routine for all `RZ` files open in write mode. Failure to do may result in the files being incompletely written or corrupted.

Data structure I/O with direct access files

```
    CALL GRIN  (CHOBJ,IDVERS*,CHOPT)
```

CHOBJ   (`CHARACTER*(4)`) name of the data structure to read in, see [`IOPA300`] for more information on this;

IDVERS   (`INTEGER`) version of the data structure to be read in, if 0 it will read any version, on output it contains the version of the data structure read in;

CHOPT   (`CHARACTER*(*)`) option:

    I   perform read only if `CHOBJ` is an initialisation data structure;

    K   perform read only if `CHOBJ` is `KINE` or `TRIG`;

    T   perform read only if `CHOBJ` is `DIGI`, `HEAD`, `HITS`, `KINE`, `VERT` or `JXYZ`;

    Q   quiet option, no message is printed;

This routine reads `GEANT` data structures from the current working directory of an `RZ` file (see the `ZEBRA` documentation for a clarification of this concept). Example:

```
    CALL GRFILE(1,'Geometry.dat',' ')
    CALL GRIN ('VOLU',1,' ')
    CALL GRIN ('MATE',1,' ')
    CALL GRIN ('TMED',1,' ')
    CALL GRIN ('ROTM',1,' ')
    CALL GRIN ('PART',1,' ')
    CALL GRIN ('SCAN',1,' ')
    CALL GRIN ('SETS',1,' ')
```

The same result can be achieved by:

```
    CALL GRFILE(1,'Geometry.dat','I')
```

```
    CALL GROUT  (CHOBJ,IDVERS,CHOPT)
```

The meaning of the arguments is the same than in the previous routine `GRIN`, but for writing instead than for reading.

This routine writes `GEANT` data structures into the current working directory of an `RZ` file (see the `ZEBRA` documentation for a clarification of this concept). Note that if the cross-sections and energy loss tables are available in the data structure `JMATE`, then they are saved on the data base. The data structures saved by this routine can be retrieved with the routine `GRIN`. Before calling this routine a
tt RZ data base must have been created using `GRFILE`. The data base must be closed with `RZEND`. Example:

```
    CALL GRFILE(1,'Geometry.dat','N')
    CALL GROUT ('VOLU',1,' ')
    CALL GROUT ('MATE',1,' ')
    CALL GROUT ('TMED',1,' ')
```

```
CALL GROUT ('ROTM',1,' ')
CALL GROUT ('PART',1,' ')
CALL GROUT ('SCAN',1,' ')
CALL GROUT ('SETS',1,' ')
```

The same result can be achieved by:

```
CALL GRFILE(1,'Geometry.dat','NO')
```

The interactive version of tt GEANT provides facilities to interactively update, create and display objects.
The routines GRGET and GRSAVE are obsolete and should not be used.

Section `KINE`

</div>

This section describes the `GEANT` kinematics structures `JVERTX` and `JKINE` and the routines which permit one to store and retrieve the information. It also contains a short description of the `GEANT` interface to the `JETSET` generator and related routines.

Storing and retrieving vertex and track parameters

```
    CALL GSVERT  (VERT,NTBEAM,NTTARG,UBUF,NUBUF,NVTX*)
```

VERT   (REAL) array of 3 containing the position of the vertex in the MRS;
NTBEAM   (INTEGER) beam track number origin of the vertex (0 if none exists);
NTTARG   (INTEGER) target track number origin of the vertex (0 if none exists);
UBUF   (REAL) user array of NUBUF user words to be stored in the data structure together with the vertex;
NWBUF   (INTEGER) number of user words;
NVTX   (INTEGER) number of the vertex stored (0 in case of error).

This routine stores the parameters of a vertex to which tracks should be attached via calls to GSKINE. Vertices are stored in the JVERTX data structure (see [KINE199]) and they are preserved for the whole duration of the event.

GEANT tracks one vertex at a time: all the particles of one vertex, and all the secondaries generated thereof must be transported before the particles of the next vertex are considered.

This routine should be called only from GUKINE when the initial kinematics of the event is defined. During tracking it is possible to add vertices to the JVERTX data structure, but this should be done via the GSKING routine and the appropriate variables in the /GCKING/ common block. Please see [TRAK300] for more information.

```
    CALL GSVERU  (NVTX,NUBUF,UBUF,IADR*)
```

NVTX   (INTEGER) vertex number;
NUBUF   (INTEGER) number of user words;
UBUF   (REAL) array of user words;
IADR   (INTEGER) position where information is stored in the user bank of the vertex.

This routine stores the first NUBUF words of array BUF in the user bank attached to vertex NVTX, starting at location IADR+1. On exit IADR is set to IADR+NUBUF, allowing subsequent filling. This allows effectively to *add* information to an existing vertex, whether or not it has already an user buffer. This is the only way to add user information to a vertex which has been created at tracking time by the routine GSKING via an appropriate setting of parameters in the common /GCKING/.

```
    CALL GFVERT  (NVTX,VERT*,NTBEAM*,NTTARG*,TOFG*,UBUF*,NUBUF*)
```

Retrieves vertex parameters. The parameters have the same meaning than the ones of GSVERT.

TOFG   (REAL) time of flight when the vertex was created;

```
    CALL GPVERT  (IVTX)
```

Prints vertex parameters.

IVTX   (INTEGER) vertex number to be printed, all vertices if IVTX=0;

```
    CALL GSKINE  (PLAB,IPART,NV,UBUF,NUBUF,NT*)
```

PLAB   (REAL) array of 3 containing the components of the momentum of the particle in GeV c^{-1};

IPART	(INTEGER) particle code (see [CONS300]);
NV	(INTEGER) number of the vertex origin of track;
UBUF	(REAL) array of NUBUF user words to be stored with the track;
NUBUF	(INTEGER) number of user words;
NT	(INTEGER) number of the stored track (0 in case of error).

This routine stores the parameters of a track in the JKINE data structure (see [KINE199]). This data structure survives for the whole event, and it is wiped out by GTRIGI at the beginning of each new event. There are two reasons to store tracks in the JKINE data structure:

- at the beginning of an event, from within GUKINE, to define the initial kinematics of the event, i.e. the particles which GEANT will transport. This must be done through GSKINE after that the vertices from which the particles originate have been defined through GSVERT;

- during tracking, to preserve the kinematic information of a particular track till the end of the current event. In this case the user should not call GSKINE directly, but rather set the appropriate flags in the /GCKING/ common block and call GSKING. This is explained in detail in [TRAK300].

        CALL **GSKINU**   (NT,NUBUF,UBUF,IADR*)

NT	(INTEGER) track number;
NUBUF	(INTEGER) number of user words;
UBUF	(REAL) array of user words;
IADR	(INTEGER) position where information is stored in the user bank of the track.

This routine stores the first NUBUF words of array BUF in the user bank attached to track NT, starting at location IADR+1. On exit IADR is set to IADR+NUBUF, allowing subsequent filling. This allows effectively to *add* information to an existing track, whether or not it has already an user buffer. This is the only way to add user information to a track which has been created at tracking time by the routine GSKING via an appropriate setting of parameters in the common /GCKING/.

        CALL **GFKINE**   (ITRA,VERT*,PVERT*,IPART*,NVERT*,UBUF*,NUBUF*)

Retrieves long-life track parameters. The parameters have the same meaning than the ones of GSKINE.

        CALL **GPKINE**   (ITRA)

Prints initial track parameters.

| ITRA | (INTEGER) track to be printed, all tracks if IVTX=0; |

The data structures `JVERTX` and `JKINE`
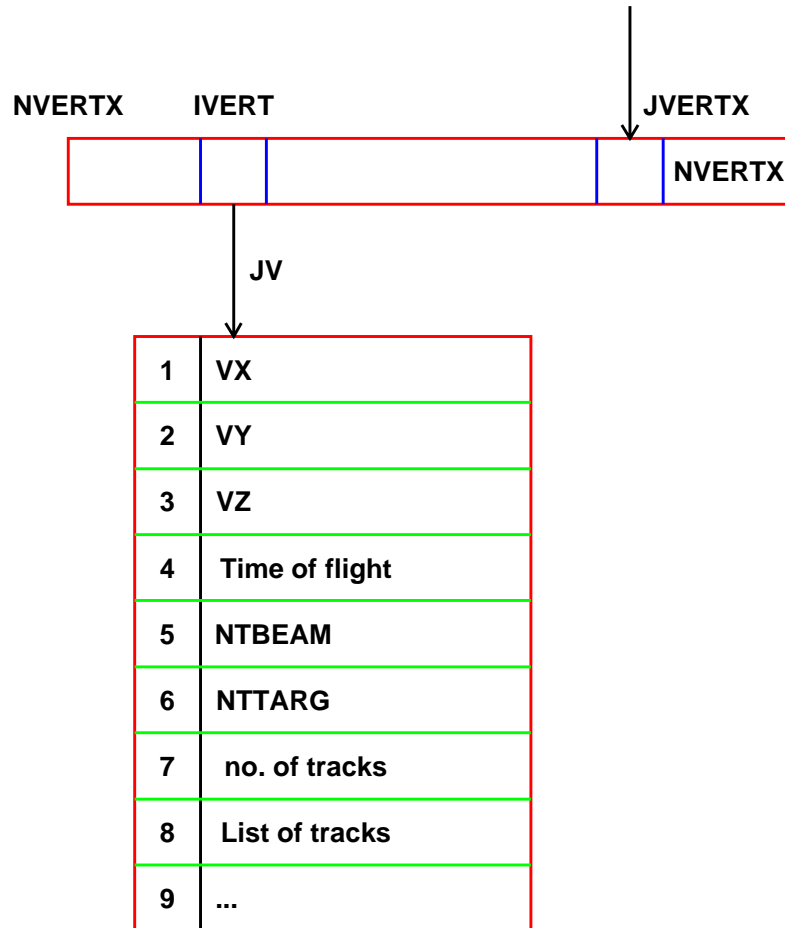

Figure 35: Layout of the `JVERTX` data structure

`JV`   = LQ(JVERTX-IVERT) pointer to the bank of vertex `IVERT`.
`JVU`   = `LQ(JV-1)` pointer to the user part of the bank.

The `JVERTX` banks are filled by the routine `GSVERT` and `GSVERU`. Vertex parameters can be retrieved by the routine `GFVERT` and printed by the routine `GPVERT`.
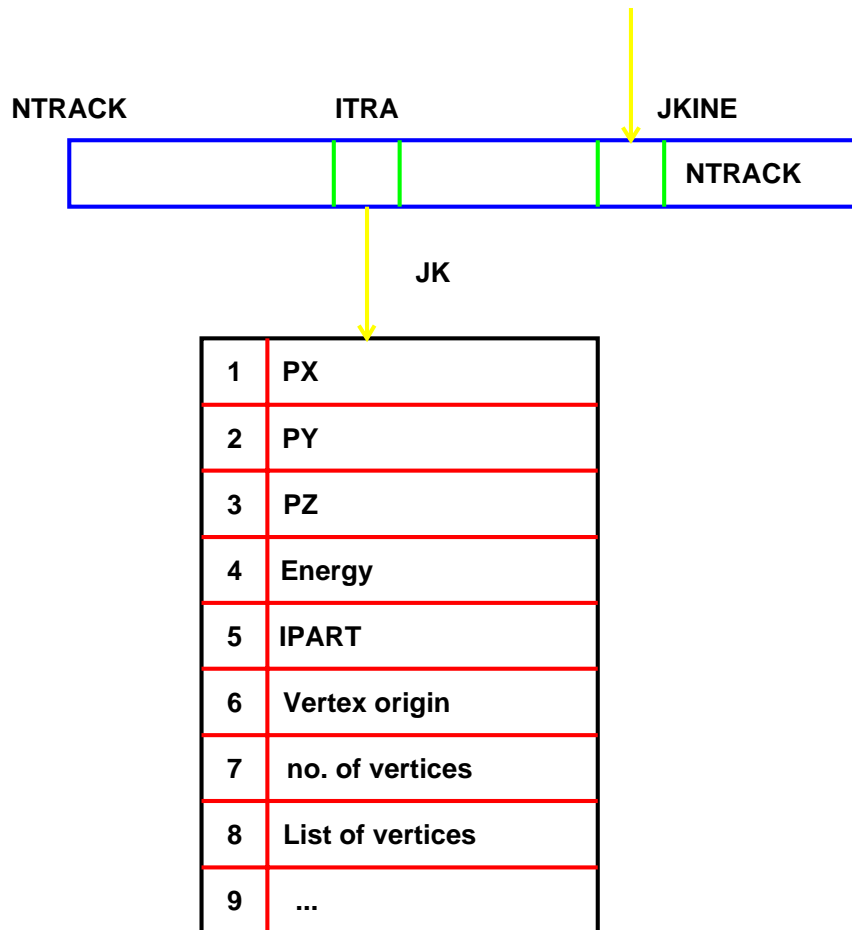

Figure 36: Layout of the `JKINE` data structure

JK   = `LQ(JKINE-ITRA)` pointer to the bank of track `ITRA`.

JKU   = `LQ(JK-1)` pointer to the user part of the bank.

The `JKINE` banks are filled by the routine `GSKINE` and `GSKINU`. Track parameters can be retrieved by the routine `GFKINE` and printed by the routine `GPKINE`.

Interface to the Lund Monte Carlo

GEANT contains a simple interface to the JETSET Monte Carlo generator [1]. This interface is composed by an initialisation routine and an event generation routine.

CALL **GLUNDI**

This is the initialisation routine which should be called before the call to GFFGO, as it defines the data record LUND. This routine performs the following actions:

1. sets ECLUND$= \sqrt{s} = 92.25$ GeV;

2. sets IFLUND$= 0$;

3. activates initial state radiative effects MSTJ(107)= 1;

4. declares some particles (K_s^0, $\Sigma^\pm$, $\Xi^\pm$, Λ^0, Ω^-) to be stable in JETSET so that GEANT can handle their tracking and decays:

```
MDCY(LUCOMP(310) ,1)=0
MDCY(LUCOMP(3222),1)=0
MDCY(LUCOMP(3112),1)=0
MDCY(LUCOMP(3322),1)=0
MDCY(LUCOMP(3312),1)=0
MDCY(LUCOMP(3122),1)=0
MDCY(LUCOMP(3334),1)=0
```

Variables ECLUND, total energy in the CMS, and IFLUND, quark flavours produced, are used as arguments for LUEEVT called by GLUND and they can be changed via the LUND data record (see [BASE040]).

CALL **GLUND**

Generate a e^-e^+ collision via the JETSET MonteCarlo and stores the resulting final state particles for transport by GEANT. All particles are attached to a vertex in (0.,0.,0.). The K and P arrays containing the full JETSET event are copied in the user buffer of the generated vertex, with the K variables converted into REAL numbers. The content of the user buffer is the following:

```
UBUF(1)             527.0
UBUF(2)     N number of particles
UBUF(3)        K(1,1) ⎫
UBUF(4)        K(1,2) ⎪
UBUF(5)        K(1,3) ⎪
UBUF(6)        K(1,4) ⎪
UBUF(7)        K(1,5) ⎪
UBUF(8)        P(1,1) ⎬  N times
UBUF(9)        P(1,2) ⎪
UBUF(10)       P(1,3) ⎪
UBUF(11)       P(1,4) ⎪
UBUF(12)       P(1,5) ⎭
```

$\tau^{\pm}$ generation and decay

CALL **GALL GTAU**

This routine is now dummy and it will only print an error message. The appropriate routines from a generator Monte Carlo (for instance the JETSET [1] package) should be used to handle $\tau^{\pm}$ production and decay.

Introduction to the section PHYS

1   Summary of the physics processes

The computer simulation of particles traversing an experimental setup has to take into account the interactions of those particles with the material of the detector. GEANT is able to simulate the dominant processes which can occur in the energy range **from 10 keV to 10 TeV** for electromagnetic interactions. As far as hadronic interactions are concerned, the range of validity is the one of the hadronic packages used, which usually does not extend below a few tens of MeV. For more information the user is invited to consult the relevant documentation [1, 2, 3, 4, 5, 6].

Simulating a given process means:

– Evaluating the probability of occurrence of the process, by sampling the **total cross-section** of the process.
– Generating the final state after interaction, by sampling the **differential cross-section** of the process.
– In case of (quasi-)continuous processes, e.g. CSDA (Continuous Slowing Down Approximation), energy losses or multiple scattering, computing the mean values of some characteristic quantities.

In Table 1 below we summarise all the processes currently implemented in GEANT, with a reference to the corresponding sections.

1.1   Simulated Processes

Hadronic Interactions

To simulate the interactions of hadrons with the nuclei of the matter traversed, two alternatives are provided:

1. The generator of the FLUKA [2, 3] hadron shower MonteCarlo and the interface routines to GEANT. See [PHYS520] for more information.

2. The generator of the GHEISHA [1] hadron shower MonteCarlo and the interface routines to GEANT. See [PHYS510] for more information.

The code both of the GHEISHA and of the FLUKA generators is contained in the GEANT library. Users should be aware that the routines of these packages do not follow the GEANT naming conventions and therefore they can clash with the names of user procedures.

Electromagnetic Processes

By means of systematic fits to the existing data, the cross-sections of the electromagnetic processes are well reproduced (within a few percent) from 10 keV up to 100 GeV, both for light (low Z) and for heavy materials.

This feature, together with the use of the interface with one of the hadronic shower generators available, makes GEANT useful also for shower simulation in gases.

Muonic interactions

Muonic interactions are simulated up to 10 TeV, making GEANT useful for cosmic rays studies.

Ionisation by charged particles

The following alternatives are provided to simulate this process:

- Sampling from the appropriate distribution around the mean value of the energy loss (`[PHYS332]`).

- Explicit generation of δ-rays (see `[PHYS330/331/430]`) and restricted fluctuations below the energy threshold for the production of δ-rays.

- Sampling the contribution of single collisions from statistical distributions. This can be used as an alternative to the first one when simulating energy losses in very thin layers (small value of g cm^{-2}) (see `[PHYS334]`).

Full Landau fluctuations and generation of δ-rays cannot be used together in order to avoid double counting of the fluctuations. An automatic protection has been introduced in `GEANT` to this effect. See `[PHYS333/332]` and `[BASE040]` for further information.

Multiple Scattering

Two methods are provided:

1. Molière distribution or plural scattering (`[PHYS325]`, `[PHYS328]`).

2. Gaussian approximation (`[PHYS320]`).

The JMATE data structure

In order to save time during the transport of the particles, relevant energy-dependent quantities are tabulated at the beginning of the run, for all materials, as functions of the kinetic energy of the particle. In particular, the inverse of the total cross-sections of all processes involving photons, electrons and muons and the dE/dx and range tables for electrons, muons and protons are calculated. The actual value of, say, the interaction length for a given process (i.e. the inverse of the macroscopic cross section) is then obtained via a linear interpolation in the tables. The data structure which contains all this information in memory is supported by the link `JMATE` in the `/GCLINK/` common block. See `[PHYS100]` and `[CONS199]` for a more information on these tables.

Probability of Interaction

The total cross-section of each process is used at tracking time to evaluate the probability of occurrence of the process. See `[PHYS010]` for an explanation of the method used.

Note: The section `PHYS` is closely related to the section `CONS`. Users wishing to have a complete overview of the physics processes included in `GEANT` should read both sections.

1.2   Control of the physical processes

For most of the individual processes the default option (indicated below) can be changed via data records `[BASE040]`. The processes are controlled via a control variable which is in the common `/GCKING/`. If not otherwise noted, the meaning of the control variable is the following:

= 0   The process is completely ignored.

= 1   The process is considered and possible secondary particles generating from the interaction are put into the `/GCKING/` common. If the interacting particle disappears in the interaction, then it is stopped with `ISTOP=1` (common `/GCTRAK/`)

= 2   The process is considered. If secondary particles result from the interaction, they are not generated and their energy is simply added in the variable `DESTEP` (common `/GCTRAK/`. If the interacting particle disappears in the interaction, the variable `ISTOP` is set to 2.

Below are listed the data record keywords, the flag names and values, and the resulting action:

Keyword   Related process

`DCAY`   Decay in flight. The decaying particles stops. The variable `IDCAY` controls this process.

     `IDCAY =0`   No decay in flight.
         `=1`   (**D**) Decay in flight with generation of secondaries.
         `=2`   Decay in flight without generation of secondaries.

`MULS`   Multiple scattering. The variable `IMULS` controls this process.

     `IMULS =0`   No multiple scattering.
         `=1`   (**D**) Multiple scattering according to Molière theory.
         `=2`   Same as `1`. Kept for backward compatibility.
         `=3`   Pure Gaussian scattering according to the Rossi formula.

`PFIS`   Nuclear fission induced by a photon. The photon stops. The variable `IPFIS` controls this process.

     `IPFIS =0`   (**D**) No photo-fission.
         `=1`   Photo-fission with generation of secondaries.
         `=2`   Photo-fission without generation of secondaries.

`MUNU`   Muon-nucleus interactions. The muon is not stopped. The variable `IMUNU` controls this process.

     `IMUNU =0`   No muon-nucleus interactions.
         `=1`   (**D**) Muon-nucleus interactions with generation of secondaries.
         `=2`   Muon-nucleus interactions without generation of secondaries.

`LOSS`   Continuous energy loss. The variable `ILOSS` controls this process.

     `ILOSS =0`   No continuous energy loss,IDRAY is forced to 0.
         `=1`   Continuous energy loss with generation of δ-rays above `DCUTE` (common `/GCUTS/`) and restricted Landau fluctuations below `DCUTE`.
         `=2`   (**D**) Continuous energy loss without generation of δ-rays and full Landau-Vavilov-Gauss fluctuations. In this case the variable `IDRAY` is forced to 0 to avoid double counting of fluctuations.
         `=3`   Same as 1, kept for backward compatibility.
         `=4`   Energy loss without fluctuation. The value obtained from the tables is used directly.

`PHOT`   Photoelectric effect. The interacting photon is stopped. The variable `IPHOT` controls this process.

     `IPHOT =0`   No photo-electric effect.
         `=1`   (**D**) Photo-electric effect with generation of the electron.
         `=2`   Photo-electric effect without generation of the electron.

`COMP`   Compton scattering. The variable `ICOMP` controls this process.

     `ICOMP =0`   No Compton scattering.
         `=1`   (**D**) Compton scattering with generation of e^-.
         `=2`   Compton scattering without generation of e^-.

`PAIR`   Pair production. The interacting γ is stopped. The variable `IPAIR` controls this process.

     `IPAIR =0`   No pair production.
         `=1`   (**D**) Pair production with generation of e^-/e^+.
         `=2`   Pair production without generation of e^-/e^+.

`BREM`   bremsstrahlung. The interacting particle (e^-, e^+, μ^+, μ^-) is not stopped. The variable `IBREM` controls this process.

     `IBREM =0`   No bremsstrahlung.
         `=1`   (**D**) bremsstrahlung with generation of γ.

	=2	bremsstrahlung without generation of γ.
RAYL		Rayleigh effect. The interacting γ is not stopped. The variable IRAYL controls this process.
	IRAYL =0	**(D)** No Rayleigh effect.
	=1	Rayleigh effect.
DRAY		δ-ray production. The variable IDRAY controls this process.
	IDRAY =0	No δ-rays production.
	=1	**(D)** δ-rays production with generation of e^-.
	=2	δ-rays production without generation of e^-.
ANNI		Positron annihilation. The e^+ is stopped. The variable IANNI controls this process.
	IANNI =0	No positron annihilation.
	=1	**(D)** Positron annihilation with generation of photons.
	=2	Positron annihilation without generation of photons.
HADR		Hadronic interactions. The particle is stopped in case of inelastic interaction, while it is not stopped in case of elastic interaction. The variable IHADR controls this process.
	IHADR =0	No hadronic interactions.
	=1	**(D)** Hadronic interactions with generation of secondaries.
	=2	Hadronic interactions without generation of secondaries.
	>2	Can be used in the user code GUPHAD and GUHADR to chose a hadronic package. These values have no effect on the hadronic packages themselves.
LABS		Light ABSorption. This process is the absorption of light photons (particle type 7) in dielectric materials. It is turned on by default when the generation of Čerenkov light is requested (data record CKOV). For more information see [PHYS260].
	ILABS =0	No absorption of photons.
	=1	Absorption of photons with possible detection.
STRA		This flag turns on the collision sampling method to simulate energy loss in thin materials, particularly gases. For more information see [PHYS334].
	ISTRA =0	**(D)** Collision sampling switched off.
	=1	Collision sampling activated.
SYNC		Synchrotron radiation in magnetic field.
	ISYNC =0	**(D)** The synchrotron radiation is not simulated.
	=1	Synchrotron photons are generated, at the end of the tracking step.
	=2	Photons are not generated, the energy is deposit locally.
	=3	Synchrotron photons are generated, distributed along the curved path of the particle.

Table 1.1: Processes currently implemented in `GEANT`

Compute the occurrence of a process

1   Principle

The simulation of the processes which accompany the propagation of a particle through the material of the detector (e.g. bremsstrahlung, δ-rays production, Compton scattering and so on) is performed by `GEANT` in the following steps:

1. Fetch a new particle to be tracked (often called *track* or *history*) from the stack supported by the link `JSTAK` (see [`TRAK399`]). This is done once at the beginning of each new track. The number of *interaction lengths* that the particle is going to travel, before undergoing each one of the possible discrete processes, is sampled at this point. These operations are done in the routine `GLTRAC`.

2. Evaluate the distance to the interaction point. This is done by the individual tracking routines (`GTGAMA`, `GTNEUT`, `GTHADR`, `GTNINO`, `GTMUON`, `GTHION` and `GTCKOV`) which control the tracking of particular particles. The number of interaction lengths remaining to travel before each of the possible processes (often called *tracking mechanisms* or simply *mechanisms*) is multiplied by the inverse of the macroscopic cross-section for that process in the current material (i.e. the interaction length). This gives the distances that the particle has to travel before each of the processes occurs in the current medium. The minimum among these numbers is the *step* over which the particle will be transported. In addition to the physics mechanisms, four *pseudo-interactions* are taken into account in the calculation of the step:

   (a) boundary crossing. The crossing of a volume boundary is treated like a discrete process. A particle never crosses a boundary during a step but rather stops there (`NEXT` mechanism);

   (b) maximum step limit. For each tracking medium a value for the maximum step can be specified by the user. Process `SMAX`;

   (c) maximum fraction of continuum energy loss, maximum angular deviation in magnetic field or maximum step for which the Molière formula, to simulate multiple scattering is valid. These are continuous processes, which introduce a limitation on the tracking step expressed by a single variable (see section [`PHYS325`] on `GMULOF`).

   (d) energy and time cut. Charged particles in matter are stopped when their energy falls below their energy threshold or when their time of flight exceeds the time cut;

   More information is given in the individual sections explaining the implementation of the physical processes.

3. Transport the particle either along a straight line (if no magnetic field or for a neutral particle) or along a helicoidal path (for charged particles in magnetic field).

4. Update the energy of the particle if continuous energy loss was in effect (charged particles in matter).

5. If a physical discrete process has been selected, generate the final state of the interaction.

6. If the incident particle *survives* the interaction (Compton, δ-rays production, bremsstrahlung, direct pair production by μ and μ-nucleus interaction, hadronic elastic scattering), sample again the number of interaction lengths to travel before the next event of the same kind. This is generally done by specialised routines: `GMUNU`, `GCOMP`, `GBREM`, etc.

7. Update the number of interaction lengths for all the processes and go back to (2) till the particle either leaves the detector or falls below its energy threshold or beyond its time cut or disappears in an interaction.

2 Distance evaluation

2.1 The interaction length

Let $\sigma(E, Z, A)$ be the total microscopic cross section for a given interaction. The mean free path, λ, for a particle to interact is given by:

$$\lambda = \frac{1}{\Sigma} \tag{1}$$

where Σ is the macroscopic cross-section in cm^{-1}. This quantity is given for an element by:

$$\Sigma = \frac{N_{Av}\rho\sigma(E, Z, A)}{A} \tag{2}$$

and for a compound or a mixture by:

$$\Sigma = \frac{N_{Av}\rho\sum_i n_i\sigma(E, Z_i, A_i)}{\sum_i n_i A_i} = N_{Av}\rho\sum_i \frac{p_i}{A_i}\sigma(E, Z_i, A_i) \tag{3}$$

N_{Av} Avogadro's number (6.02486×10^{23})
Z atomic number
A atomic weight
ρ density
σ total cross-section for the reaction
n_i proportion by number of the ith element in the material
p_i $= n_i A_i / \sum_j n_j A_j$, proportion by weight of the ith element in the material

For electromagnetic processes which depend linearly on the atomic number Z we can write:

$$\begin{aligned}
\Sigma(E) &= N_{Av}\rho\sum_i \frac{p_i}{A_i}\sigma(E, Z_i) = N_{Av}\rho\sum_i \frac{p_i}{A_i} Z_i f(E) \\
&= N_{Av}\rho f(E)\sum_i \frac{p_i}{A_i} Z_i = N_{Av}\rho f(E) Z_{eff} \\
Z_{eff} &= \sum_i \frac{p_i}{A_i} Z_i
\end{aligned}$$

the value above of Z_{eff} is calculated by `GPROBI`. This mean free path is tabulated at initialisation time as a function of the kinetic energy of the particle, or, for hadronic interactions, it is calculated at tracking time.

Cross sections are tabulated in the energy range defined as: `ELOW(1)` $\leq E \leq$ `ELOW(NEK1)` in `NEK1` bins. These values can be redefined by the data record `RANGE`. Default values are `ELOW(1)` $= 10keV$, `ELOW(NEK1)` $= 10TeV$ and `NEKBIN` $= $ `NEK1` $- 1 = 90$. `NEKBIN` cannot be bigger than 199. The array `ELOW` is in the common `/GCMULO/`.

Numerically, if we measure the microscopic cross section in b where $1b = 10^{-24}cm^{-2}$, we can express the macroscopic cross section as:

$$\Sigma[cm^{-1}] = \frac{6.02486 \times 10^{23}\rho[g\ cm^{-3}]\sigma(E, Z, A)[b] \times 10^{-24}}{A} \tag{4}$$

$$= 0.602486 \frac{\rho[g\ cm^{-3}]}{A}\sigma(E, Z, A)[b] \tag{5}$$

which is the formula mostly used in `GEANT`.

2.2 Determination of the interaction point

The mean free path of a particle for a given process, λ, depends on the medium and cannot be used directly to sample the probability of an interaction in a heterogeneous detector. The number of mean free paths which a particle travels is:

$$N_\lambda = \int \frac{dx}{\lambda(x)}$$

and it is independent of the material traversed. If N_R is a random variable denoting the number of mean free paths from a given point until the point of interaction, it can be shown that N_R has the distribution function

$$P(N_R < N_\lambda) = 1 - e^{-N_\lambda}$$

The total number of mean free paths the particle travels before the interaction point, N_λ, is sampled at the beginning of the trajectory as:

$$N_\lambda = -\log(\eta)$$

where η is a random number uniformly distributed in the range $(0, 1)$. N_λ is updated after each step Δx according the formula:

$$N'_\lambda = N_\lambda - \frac{\Delta x}{\lambda(x)}$$

until the step originating from $s(x) = N_\lambda \lambda(x)$ is the shortest and this triggers the specific process.

3 Common `/GCPHYS/`

The variables described above are stored in the common `/GCPHYS/`, one process per line:

```
      COMMON/GCPHYS/IPAIR,SPAIR,SLPAIR,ZINTPA,STEPPA
     +             ,ICOMP,SCOMP,SLCOMP,ZINTCO,STEPCO
     +             ,IPHOT,SPHOT,SLPHOT,ZINTPH,STEPPH
     +             ,IPFIS,SPFIS,SLPFIS,ZINTPF,STEPPF
     +             ,IDRAY,SDRAY,SLDRAY,ZINTDR,STEPDR
     +             ,IANNI,SANNI,SLANNI,ZINTAN,STEPAN
     +             ,IBREM,SBREM,SLBREM,ZINTBR,STEPBR
     +             ,IHADR,SHADR,SLHADR,ZINTHA,STEPHA
     +             ,IMUNU,SMUNU,SLMUNU,ZINTMU,STEPMU
     +             ,IDCAY,SDCAY,SLIFE ,SUMLIF,DPHYS1
     +             ,ILOSS,SLOSS,SOLOSS,STLOSS,DPHYS2
     +             ,IMULS,SMULS,SOMULS,STMULS,DPHYS3
     +             ,IRAYL,SRAYL,SLRAYL,ZINTRA,STEPRA
      COMMON/GCPHLT/ILABS,SLABS,SLLABS,ZINTLA,STEPLA
     +             ,ISYNC
     +             ,ISTRA
*
```

The first 9 processes (from `PAIR` production up to `MUon NUclear` interaction) and the `RAYLeigh` scattering and Light `ABSorbtion` have the same scheme. Let's take as an example the first one (for a complete description of the common see [ZZZZ010]):

`IPAIR`   flag for secondaries:

        `0=`   the process is turned off;

        `1=`   generation of secondaries enabled;

2=   no generation of secondaries.

SPAIR $N_\lambda \lambda(x)$ = remaining track-length before interaction, evaluated at the last point where the mechanism was active, i.e. IPAIR≠ 0.

SLPAIR track length at the time when the interaction last happened for the current particle. Only SLPAIR (direct pair production by μ), SLDRAY (δ-ray production), SLBREM (bremsstrahlung for μ), SLHADR (hadronic interactions), SLMUNU (muon-nucleus interactions) and SLRAYL (Rayleigh effect) are used. The variables SOLOSS, STLOSS, SOMULS, STMULS are obsolete. They have been kept for backward compatibility, but their value is undefined and should not be used.

ZINTPA N_λ = remaining number of interaction lengths (mean free paths) evaluated at the last point where the mechanism was active, i.e. IPAIR≠ 0.

STEPPA $\lambda(x)$ = value of the interaction length at the last point where the mechanism was active, i.e. IPAIR≠ 0;

The evaluation and update of the quantities like STEPPA, SPAIR and ZINTPA are turned off in the media where the mechanism is not active (IPAIR ≠ 0). Turning off a mechanism in one tracking medium may give incorrect physics results because not only will the mechanism not be active, but the interaction probabilities will not be updated, as if that medium had not been traversed at all. This feature of the tracking routines is used mainly in the vacuum, (defined as a medium with atomic number Z < 1), where all the mechanisms but DECAy (and SYNChrotron radiation, if activated) are inactive.

The DECAy in flight is simpler since the mean life time of the particle, τ, is not material dependent and can be sampled directly.

SLIFE   not used.

SUMLIF proper time left before the decay. At the beginning of the track SUMLIF = $-c\tau \log(\eta)$.

SDCAY   distance left to decay point evaluated at the last point where the mechanism was active, i.e. IDECA ≠ 0.

4   Cross-section, energy loss and range tables

Cross-sections, energy loss dE/dx and range $R(E_{kin})$ are tabulated for all materials which enter in the definition of a tracking medium by the routine GPHYSI. The values of the energy for which the tabulated quantities are calculated are stored in the common /GCMULO/ (see [ZZZZ010]). To evaluate one of the tabulated quantities for a particle of *kinetic* energy E_0, a linear interpolation is used. Let i be such that:

$$E_i < E_0 \leq E_{i+1}$$

The integer variable IEKBIN in common /GCTRACK/ is equal to i during tracking and its value is recomputed by the routine GEKBIN when the energy of the particle changes. If the quantity Y has been tabulated so that $Y_i = Y(E_i)$ then the value $Y_0 = Y(E_0)$ is calculated as:

$$Y_0 = Y_i + \frac{E_0 - E_i}{E_{i+1} - E_i}(Y_{i+1} - Y_i) = Y_i\left(1 - \frac{E_0 - E_i}{E_{i+1} - E_i}\right) + Y_{i+1}\frac{E_0 - E_i}{E_{i+1} - E_i} \tag{6}$$

Inside the code the following quantities are used:

$$\text{GEKRAT} = \frac{E_0 - E_i}{E_{i+1} - E_i} \qquad\qquad \text{GEKRT1} = \left(1 - \frac{E_0 - E_i}{E_{i+1} - E_i}\right)$$

where GEKRAT is in common /GCTRAK/ and GEKRT1 is a local variable recomputed when needed.

5 The energy loss tables

Energy loss and multiple scattering are continuous processes that are applied at every step for charged particles in matter ($Z \geq 1$).

As explained in [`PHYS330`] and [`PHYS430`], energy loss tables are calculated at initialisation time (`GPHYSI`) for all the materials which enter in the definition of a tracking medium (see [`CONS200`]). These tables contain `NEK1` values of dE/dx calculated for the corresponding values of energy in `ELOW`.

In case of mixtures/compounds, the rule [7] is to combine the energy loss tables in GeV g^{-1} cm^2 according to the proportion by weight of the elements, that is:

$$\frac{dE}{dx} = \rho \sum_i \frac{p_i}{\rho_i} \left(\frac{dE}{dx}\right)_i$$

6 Limitations on the step size

The routine `GMULOF` called by `GPHYSI` creates and fills a table of `NEK1` values corresponding to the `ELOW` values containing the smaller of the upper limits for the step imposed by the three continuous processes: energy loss, multiple scattering and bending of the track induced by the magnetic field.

Continuous energy loss can introduce an upper limit on the step via the variable `DEEMAX`, an argument to the `GSTMED` routine. During tracking the value of `DEEMAX` for the current medium is stored in the common `/GCMATE/`. `DEEMAX` is the maximum fraction of kinetic energy which a particle can lose in a step due to continuous ionisation ($0 <$ `DEEMAX` < 1). The limitation on the step size coming from `DEEMAX` is:

$$step \leq \frac{\texttt{DEEMAX}}{dE/dx}$$

Multiple scattering as well can limit the step size, see [`PHYS325`]. The limitation is given as:

$$step \leq \min\left(T_{Bethe}, 10\ X_0\right)$$

where X_0 is the radiation length and T_{Bethe} is the maximum step for which the Molière approximation is valid (see [`PHYS325`]).

Another upper limit on the step size comes from the magnetic field. The bending of the particle trajectory in the magnetic field may be limited by the `TMAXFD` argument to the `GSTMED` routine. During tracking the value of `TMAXFD` for the current medium is stored in the common `/GCMATE/`.

A lower limitation on the tracking step is not generally imposed. There is, however, a protection against the step being reduced to a very small value by continuous processes. In particular multiple scattering at low energies (< 1 MeV) can impose a very small tracking step with serious consequences on the tracking time. To avoid this, a lower limit on the step imposed by continuous processes is introduced: `STMIN`. The meaning of `STMIN` is the following: below 1 MeV the stopping range is usually small. If the stopping range becomes smaller than `STMIN`, the constraint imposed by the multiple scattering is ignored and the minimum is taken between the reduced stopping range (the distance the particle has to travel to reach its threshold energy) and `STMIN` itself. In this sense `STMIN` is no more than a tracking accelerator for stopping particles.

Another limitation on the step size which is imposed by the tracking routines during transport is the `STEMAX` parameter of `GSTMED` which sets an absolute upper limit to the size of a step for each tracking medium.

7 Automatic calculation of parameters

The definition of a *tracking medium* requires the specification by the user of a set of parameters (see [`CONS200`]) which can critically affect the tracking and hence the physics results of the `GEANT` MonteCarlo. To help the user to find the optimal set of parameters, by default `GEANT` overrides the values of `STMIN`, `DEEMAX`, `STEMAX` and `TMAXFD`. This behaviour is controlled by the `AUTO` data record and interactive command. By default `AUTO=1` and automatic evaluation of the parameters is enforced (see below for the partly anomalous behaviour of `TMAXFD`). When `AUTO= 0` then only those parameters which are < 0 are recalculated by `GEANT`, while for the others the user input is accepted with minimal checking.

When the automatic calculation of parameters is active, the following applies:

DEEMAX The formula used by GEANT is the following:

$$
\text{DEEMAX} = \begin{cases} 0.25 & \text{if } \texttt{ISVOL} = 0 \quad \text{and} \quad X_0 < 2\,\text{cm} \\[2mm] 0.25 - \dfrac{0.2}{\sqrt{X_0}} & \text{if } \texttt{ISVOL} = 0 \quad \text{and} \quad X_0 \geq 2\,\text{cm} \\[2mm] \dfrac{0.2}{\sqrt{X_0}} & \text{if } \texttt{ISVOL} \neq 0 \end{cases}
$$

ISVOL > 0 defines a *sensitive* detector, while ISVOL ≤ 0 is a non-*sensitive* detector (see [HITS]).

STMIN The default value corresponds to a stopping range of 200 keV above CUTELE.

TMAXFD The default value corresponds to $20°$ if the input value to GSTMED is ≤ 0 or $> 20°$, otherwise the input value is taken.

STEMAX The default value is 10^{10} (BIG variable in common /GCONST/).

These values have been tuned empirically on a variety of setups and users are invited to start with automatic computation. The values of the parameters can be checked with a call to GPRINT('TMED',0) after GPHYSI has been called. Use of AUTO mode is strongly recommended because it makes GEANT a predictive tool. In this way all parameters are automatically computed by the system as opposed to tuning data and MonteCarlo via the tracking parameters.

8   Energy loss

8.1   Energy loss tables

In previous versions of GEANT (up to version 3.13) the energy lost by a charged particle travelling through matter was calculated by the formula:

$$
\Delta E = \frac{dE}{dx} \times step
$$

The quantity dE/dx was calculated and tabulated for $e^\pm$, $\mu^\pm$ and protons and the value for a particle of a given energy E_0 was calculated interpolating linearly the tables:

$$
\left. \frac{dE}{dx} \right|_{E=E_0} = \left. \frac{dE}{dx} \right|_{E=E_i} + \frac{E_0 - E_i}{E_{i+1} - E_i} \left(\left. \frac{dE}{dx} \right|_{E=E_{i+1}} - \left. \frac{dE}{dx} \right|_{E=E_i} \right) \tag{7}
$$

$$
= \texttt{GEKRT1} \times \left. \frac{dE}{dx} \right|_{E=E_i} + \texttt{GEKRAT} \times \left. \frac{dE}{dx} \right|_{E=E_{i+1}} \qquad (E_i < E_0 \leq E_{i+1})
$$

These formula work of course on the assumption that the error is negligible. But the error on the linear approximation is $\mathcal{O}\left(\partial^2 E / \partial x\, \partial E\right)$ which is far from negligible at low energy. In this way the energy loss at low energies was constantly underestimated and the particles could travel too far before stopping.

8.2   Stopping range tables

To correct for this problem, a different approach was introduced in GEANT version 3.14. The *stopping range* of a particle is defined as the distance that the particle will travel before stopping. By definition the stopping range for a particle of energy E_0 is given by:

$$
R = \int_{E_0}^{0} \frac{dx}{dE}\, dE = \int_{0}^{E_0} -\frac{dx}{dE}\, dE
$$

Note that in the tables the positive quantity $-dE/dx$ is stored. The method used was to build a table of stopping ranges based on ELOW by integrating the inverse of the dE/dx tables in GRANGI. At tracking time the algorithm was the following:

1. Evaluate the stopping range for the threshold energy (`STOPC`). This was done only once at the beginning of each new track.

2. From the energy of the particle derive the stopping range by a linear interpolation of the range table:

$$R_0 = \texttt{GEKRT1} \times R_i + \texttt{GEKRAT} \times R_{i+1}$$

   where $E_i < E_0 \leq E_{i+1}$.

3. Evaluate the stopping range for the particle after the step: $R_0' = R_0 - step$. If this is less than the stopping range of a particle with threshold energy, the particle is terminated as a stopping particle below the energy cut. Otherwise the following quantities are evaluated:

$$R_j < R_0' \leq R_{j+1} \qquad \texttt{GEK} = \frac{R_0' - R_j}{R_{j+1} - R_j} \qquad \texttt{GEK1} = 1 - \texttt{GEK}$$

   and the final energy is computed as:

$$E_0' = \texttt{GEK1} \times \texttt{ELOW}(j) + \texttt{GEK} \times \texttt{ELOW}(j\texttt{+1})$$

4. the energy loss is computed as:

$$\Delta E = E_0 - E_0'$$

   This value is then corrected to take into account the energy loss fluctuations (see [`PHYS332`]).

This method has two main disadvantages. The first is due to the finite precision of computers. As the energy loss in a step is calculated as the difference of two numbers, it is subject to large relative errors. The effect can be particularly serious in the case of light materials, particles near the minimum ionisation point or with very short steps, where $\Delta E = \texttt{DESTEP}$ can even result in a negative quantity. As the relative precision of a 32-bit computer is around 10^{-6}, the error on the energy loss of a 100 GeV track can be as large as 100 keV.

The second problem connected with this method can be easily shown if we compute dE/dx as:

$$
\begin{aligned}
\frac{dE}{dx} &= \frac{d}{dx}\left(E_0 - E_0'\right) = \frac{d}{dx}\left(E_0 - \texttt{GEK1} \times \texttt{ELOW}(j) - \texttt{GEK} \times \texttt{ELOW}(j\texttt{+1})\right) \\[2mm]
&= \frac{d}{dx}\left(E_0 - E_j - \frac{R_0' - R_j}{R_{j+1} - R_j}\left(E_{j+1} - E_j\right)\right) = -\frac{d}{dx}\frac{\Delta E_j}{\Delta R_j}\left(R_0' - R_j\right) \\[2mm]
&= -\frac{\Delta E_j}{\Delta R_j}\frac{dR_0'}{dx} = \frac{\Delta E_j}{\Delta R_j}\frac{step}{dx} = \frac{\Delta E_j}{\Delta R_j}
\end{aligned}
$$

As we can see, the reconstructed dE/dx curve due to continuous energy loss is a step function and constant in each energy bin. Thus, although the results obtained with `GEANT 3.14` were very satisfactory, this was felt to be an undesirable feature.

8.3 Energy loss in `GEANT`

The two problems mentioned above have been solved in `GEANT 3.15`. As far as the precision is concerned, the solution was to revert to the algorithm of `GEANT 3.13` every time the relative energy loss in the step (`DESTEP/GEKIN`) is smaller than five times the machine precision. This has given good results without loosing the substantial improvements obtained in `GEANT 3.14` with the introduction of the stopping range algorithm. As a matter of fact, the above condition happens only the in the case of very small steps or when the dE/dx curve is very flat, and in both cases the algorithm based on the dE/dx tables is a good approximation.

The second problem has been solved by changing the interpolation algorithm, going from a linear to a quadratic interpolation. Instead of assuming a linear relation between energy and stopping range in every energy bin, we assume a quadratic relation of the sort:

$$E \; = \; f(R) \; = \; aR^2 + bR + c$$

The only problem now is the determination of the coefficients a, b and c. To do this we recall that the general formula of the parabola which passes through the points (x_1, y_1), (x_2, y_2), (x_3, y_3) is the following:

$$
\begin{aligned}
y \;&=\; \frac{(x - x_2)(x - x_3)}{(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{(x - x_1)(x - x_3)}{(x_2 - x_1)(x_2 - x_3)} y_2 + \frac{(x - x_1)(x - x_2)}{(x_3 - x_1)(x_3 - x_2)} y_3 \\
&=\; x^2 \left(\frac{y_1}{(x_1 - x_2)(x_1 - x_3)} + \frac{y_2}{(x_2 - x_1)(x_2 - x_3)} + \frac{y_3}{(x_3 - x_1)(x_3 - x_2)} \right) - \\
&\quad x \left(\frac{y_1(x_2 + x_3)}{(x_1 - x_2)(x_1 - x_3)} + \frac{y_2(x_1 + x_3)}{(x_2 - x_1)(x_2 - x_3)} + \frac{y_3(x_1 + x_2)}{(x_3 - x_1)(x_3 - x_2)} \right) + \\
&\quad \left(\frac{y_1 x_2 x_3}{(x_1 - x_2)(x_1 - x_3)} + \frac{y_2 x_1 x_3}{(x_2 - x_1)(x_2 - x_3)} + \frac{y_3 x_1 x_2}{(x_3 - x_1)(x_3 - x_2)} \right)
\end{aligned}
$$

This allows us to calculate and tabulate the coefficients a, b and c just by replacing y_i by `ELOW(I)` and x_i by the corresponding stopping range `ELOW(i)`. In the routine `GRANGI` a table of length $3 \times (\mathtt{NEKBIN} - 1)$ is created:

$$\mathtt{Q(JINTRP+3*(I-1)+1)} \;=\; a(R_I, R_{I+1}, R_{I+2}, E_I, E_{I+1}, E_{I+2}) \;=\; A_I$$

$$\mathtt{+2)} \;=\; 0.5 \, \frac{b(R_I, R_{I+1}, R_{I+2}, E_I, E_{I+1}, E_{I+2})}{a(R_I, R_{I+1}, R_{I+2}, E_I, E_{I+1}, E_{I+2})} \;=\; B_I$$

$$\mathtt{+3)} \;=\; \frac{c(R_I, R_{I+1}, R_{I+2}, E_I, E_{I+1}, E_{I+2})}{a(R_I, R_{I+1}, R_{I+2}, E_I, E_{I+1}, E_{I+2})} \;=\; C_I$$

where $E_I = \mathtt{ELOW(I)}$ and $R_I = \mathtt{R(ELOW(I))}$. The calculation of the energy loss is now done in the following steps:

1. Evaluate the stopping range for the threshold energy (`STOPC`), only once at the beginning of each new particle tracking.

2. From the energy of the particle derive the stopping range by a quadratic interpolation of the range table:

$$R_0 = -B_I + \frac{A_I}{|A_I|} \sqrt{B_I{}^2 - \left(C_I - \frac{E_0}{A_I} \right)}$$

   The value of I is chosen according to the following. Let i be such that $\mathtt{ELOW}(i) < E_0 \leq \mathtt{ELOW}(i+1)$:

$$
\mathtt{I} = \begin{cases}
\max(i - 1, 1) & \text{if } \dfrac{E_0 - \mathtt{ELOW}(i)}{\mathtt{ELOW}(i+1) - \mathtt{ELOW}(i)} < 0.7 \\[3ex]
\min(i, \mathtt{NEKBIN} - 1) & \text{if } \dfrac{E_0 - \mathtt{ELOW}(i)}{\mathtt{ELOW}(i+1) - \mathtt{ELOW}(i)} \geq 0.7
\end{cases}
$$

   The value of 0.7 is an empirical number which minimises the discontinuities of the reconstructed dE/dx curve.

3. Evaluate the stopping range for the particle after the step: $R'_0 = R_0 - step$. If this is less than the stopping range of a particle of threshold energy, the particle is terminated as a stopping particle below the energy cut. Otherwise, the final energy is computed as:

$$E'_0 = A_I \left(C_I + R'_0 \left(2B_I + R'_0 \right) \right)$$

4. the energy loss is computed as:

$$\Delta E = E_0 - E_0'$$

This value is then corrected to take into account the energy loss fluctuations (see [PHYS332]).

This method results in a dE/dx curve which is a set of connected straight lines and not a step function.

Steering routine for physics initialisation

CALL **GPHYSI**

The routine `GPHYSI` is called at initialisation time by the user usually from the `UGINIT` routine (see example in [`BASE100`]). The purpose of `GPHYSI` is twofold:

- print the parameters of the current run

- compute the cross-section and energy loss tables and fill the `JMATE` data structure [`CONS199`].

1   Print the run definitions

`GPHYSI` prints the `GEANT` version number and the `ZEBRA` [8] version number stored in the `JRUNG` data structure [`BASE299`]

`GPHYSI` also prints the tracking and physics parameters for the current run, which are stored in the `JTMED` data structure. See the description of the `JTMED` data structure in [`CONS210`] and [`CONS299`].

A summary table like below will be output by `GPHYSI`

```

***************************************************************
```

The meaning of the printed values is described in the documentation of the commons /GCCUTS/ and /GCPHYS/ in [ZZZZ010]. Different values of the parameters can be assigned by the user to each tracking medium (see [BASE100]). The parameter definition in GEANT proceeds as follows:

1. a default set of *global* values of the parameters is defined for all tracking media by the routine GINIT;

2. the default values can be changed by the user via the data records read by the routine GFFGO. A summary of all valid data records is given in [BASE040];

3. after having defined tracking media and materials, the user can redefine the parameters for **each medium** via the routine GSTPAR [CONS210];

4. if the data structures are read from an external file (see IOPA section), all the parameters are taken from this file. In this case the user can still modify them, but this should be done **before** calling the routine GPHYSI.

2   Compute cross-section and energy loss tables

GPHYSI is the steering routine to compute the cross-section and energy loss tables for all materials used as tracking media. GPHYSI builds and fills the JMATE data structure described in [CONS199]. Here, we give the flow chart of this process. The description of the specialised routines can be found in the rest of the section PHYS.

Note: if several tracking media are using the same material (for instance a calorimeter and a chamber support can be both in steel) the energy cuts must be the same. If this is not possible, the user must define materials with different numbers.

GPHYSI	Initialisation of physics processes. This routine should be called by the user before the tracking starts, but after all the material, *mechanism* flags and energy cuts have been defined. GPHYSI should also be called whenever a new initialisation data structure is read from disk.
GRNDMQ	Initialises the value of the seeds of the random number generator. See [BASE420] for more information
GEVKEV	Routine to format energy values for printout. See [BASE410] for more details.

Notes:

1. The μ-nucleus interactions are treated **either** as a continuous energy loss by the muon (IMUNU= 0) **or** as a discrete process (IMUNU$\geq$1), **in an exclusive way** i.e.:

   - If IMUNU= 0, the dE/dx due to the interactions is added to that coming from direct (e^+/e^-) pair production in the routine GPRELA.

   - If IMUNU$\geq$ 1, the total cross section is computed in GMUNUI.

2. The total cross sections for hadronic interactions cannot be tabulated at initialisation time, as they are dependent on the nature of the incident particle. They are computed at tracking time by the function FLDIST in case of FLUKA [PHYS520], GHESIG in case of GHEISHA [PHYS510] or FMDIST in case of MICAP [PHYS530].

Total cross-section for $e^- e^+$-pair production by photons

1 Subroutines

```
CALL GPRSGA
```

`GPRSGA` calculates the total cross-section for the pair production of photons and the direct pair production of muons in all materials. It tabulates the mean free path, $\lambda = 1/\Sigma$ (in cm), as a function of the medium and the energy. For the pair production by photons, it calls the function `GPRSGG`. The energy bins are the one of the array `ELOW` in common `/CGMULO/` initialised in the routine `GPHYSI`. The following pointers are used:

`JMA = LQ(JMATE-I)`   pointer to the Ith material
`JPAIR = LQ(JMA-10)`   pointer to pair production cross-sections

`GPRSGA` is called at initialisation time by `GPHYSI`.

```
VALUE = GPRSGG (Z,E)
```

`GPRSGG` calculates the total cross-section for the pair production of a photon with energy `E` in material with atomic number `Z`. It is called by `GPRSGA`.

2 Method

We have parameterised the total cross-section of $e^+ e^-$-pair production by photon as:

$$\sigma(Z, E_\gamma) = Z(Z+1)\left(F_1(X) + F_2(X)Z + F_3(X)/Z\right) \quad \text{(barn/atom)} \tag{1}$$

where

$$
\begin{aligned}
X &= \ln(E_\gamma/m), \\
m &= \text{electron mass}, \\
E_\gamma &= \text{photon energy}
\end{aligned}
$$

and

$$F_i(X) = \sum_{n=0}^{5} c_n X^n$$

The parameters c_n were taken from a least-square fit to the data [9] and can be found in the `DATA` statement in the function `GPRSGG(Z,E)` which computes the formula (1) (in barn/atom).

This parameterisation gives a good description of the data in the range:

$$
\left.
\begin{aligned}
1 &\leq Z \leq 100 \\
1.5 \text{ MeV} &\leq E_\gamma \leq 100 \text{ GeV}
\end{aligned}
\right\}
\quad \frac{\Delta \sigma}{\sigma} \leq 5\% \quad \text{with a mean value of} \approx 2.2\% \tag{2}
$$

This mean free path is tabulated at initialisation as a function of the medium and of the energy by the routine `GPRSGA`.

Simulation of e^-e^+-pair production by photons

1   Subroutines

CALL **GPAIRG**

GPAIRG generates e^-e^+-pair production by photons. It uses a modified version of the random number techniques of Butcher and Messel [10] to sample the secondary electron/positron energies from the Coulomb corrected Bethe-Heitler differential cross-section. For the angular distribution of the pair, it calls the function GBTETH.

Input: via COMMON /GCTRAK/

Output: via COMMON /GCKING/

GPAIRG is called from GTGAMA, when the photon reaches its pair production point.

VALUE = **GBTETH**   (ENER,PARTM,EFRAC)

GBTETH calculates the angular distribution of the e^-e^+-pair for pair production and of the photon for bremsstrahlung. In case of e^-e^+-pair production by photons, it gives the scaled angle for an electron (mass PARTM) of energy ENER which is EFRAC times the initial energy of the photon. GBTETH is called by GPAIRG.

2   Method

2.1   MonteCarlo technique

We give a very short summary of the random number technique used here [10, 11]. The method is a combination of the composition and rejection Monte Carlo methods. Suppose we wish to sample x from the distribution $f(x)$ and the (normalised) probability density function can be written as

$$f(x) = \sum_{i=1}^{n} \alpha_i f_i(x) g_i(x) \tag{1}$$

where $f_i(x)$ are normalised density functions, $\alpha_i > 0$ and $0 \le g_i(x) \le 1$.

According to this method, x can sampled in the following way:

1. select a random integer i such that $(1 \le i \le n)$ with probability proportional to α_i

2. select a value x' from the distribution $f_i(x)$

3. calculate $g_i(x')$ and accept $x = x'$ with probability $g_i(x')$;

4. if x' is rejected restart from step 1.

It can be shown that this scheme is correct and the mean number of tries to accept a value is $\sum_i \alpha_i$.

In practice we have a good method of sampling from the distribution $f(x)$, if

*   all the subdistributions $f_i(x)$ can be sampled easily;

*   the rejection functions $g_i(x)$ can be evaluated easily/quickly;

- the mean number of tries is not too large.

Thus the different possible decompositions of the distribution $f(x)$ are not equivalent from the practical point of view (e.g. they can be very different in computational speed) and it can be very useful to optimise the decomposition. A remark of practical importance is that if our distribution is not normalised ($\int f(x)dx = C > 0; C \approx 1$), the method can be used in the same manner, the only difference is that the mean number of tries in this case is given by $\sum_i \alpha_i / C$.

2.2 Differential cross-section for pair production

The Bethe-Heitler differential cross-section with the Coulomb correction for a photon of energy E to produce a $e^- e^+$-pair with one of the particles having energy ϵE (ϵ is the fraction of the photon energy carried by one particle of the pair) is given as in [12]:

$$\frac{d\sigma(Z, E, \epsilon)}{d\epsilon} = \frac{r_0^2 \alpha Z[Z + \xi(Z)]}{E^2} \left\{ [\epsilon^2 + (1 - \epsilon)^2][\Phi_1(\delta) - \frac{F(Z)}{2}] + \frac{2}{3}\epsilon(1 - \epsilon)[\Phi_2(\delta) - \frac{F(Z)}{2}] \right\} (2)$$

where $\Phi_i(\delta)$ are the screening functions depending on the screening variable δ

$$\delta = \frac{136m}{Z^{1/3}E} \frac{1}{\epsilon(1 - \epsilon)} \qquad m = \text{electron mass}$$

$$\left. \begin{array}{l} \Phi_1(\delta) = 20.867 - 3.242\delta + 0.625\delta^2 \\ \Phi_2(\delta) = 20.209 - 1.930\delta - 0.086\delta^2 \end{array} \right\} \qquad \delta \leq 1$$

$$\Phi_1(\delta) = \Phi_2(\delta) = 21.12 - 4.184 \ln(\delta + 0.952) \qquad \delta > 1$$

$$F(Z) = \left\{ \begin{array}{ll} 8/3 \ln Z & E < 0.05 \ GeV \\ 8/3 \ln Z + 8f_c(Z) & E \geq 0.05 \ GeV \end{array} \right.$$

$$\xi(Z) = \frac{\ln(1440/Z^{2/3})}{\ln(183/Z^{1/3}) - f_c(Z)}$$

$$f_c(Z) \qquad \qquad \text{the Coulomb correction function}$$

$$\begin{array}{rcl} f_c(Z) & = & a(1/(1 + a) + 0.20206 - 0.0369a + 0.0083 * a^2 - 0.002a^3) \\ a & = & (\alpha * Z)^2 \\ \alpha & = & 1/137 \end{array}$$

The kinematical range for the variable ϵ is

$$\frac{m}{E} \leq \epsilon \leq 1 - \frac{m}{E} \tag{3}$$

The cross-section is symmetric with respect to the interchange of ϵ with $1 - \epsilon$, so we can restrict ϵ to lie in the range $\epsilon_0 = m/E \leq \epsilon \leq 1/2$

After some algebraic manipulations we can decompose the cross-section as (note: the normalisation is not important):

$$\frac{d\sigma}{d\epsilon} = \sum_{i=1}^{2} \alpha_i f_i(\epsilon) g_i(\epsilon)$$

where

$$\alpha_1 \quad = \quad \frac{(0.5 - \epsilon_0)^2}{3} F_{10} \qquad\qquad \alpha_2 \quad = \quad \frac{1}{2} F_{20}$$

$$f_1(\epsilon) \quad = \quad \frac{3}{(0.5 - \epsilon_0)^3}(\epsilon - 0.5)^2 \qquad f_2(\epsilon) \quad = \quad \frac{1}{0.5 - \epsilon_0}$$

$$g_1(\epsilon) \quad = \quad F_1/F_{10} \qquad\qquad\qquad g_2(\epsilon) \quad = \quad F_2/F_{20}$$

and

$$F_1 \quad = \quad F_1(\delta) = 3\Phi_1(\delta) - \Phi_2(\delta) - F(Z) \qquad F_{10} \quad = \quad F_1(\delta_{min})$$

$$F_2 \quad = \quad F_2(\delta) = \frac{3}{2}\Phi_1(\delta) + \frac{1}{2}\Phi_2(\delta) - F(Z) \quad F_{20} \quad = \quad F_2(\delta_{min})$$

$$\delta_{min} \quad = \quad 4\frac{136\,m}{Z^{\frac{1}{3}}3E}$$

δ_{min} is the minimal value of the screening variable δ. It can be seen that the functions $f_i(\epsilon)$ are normalised and that the functions $g_i(\epsilon)$ are "valid" rejection functions.

Therefore, if r_i are uniformly distributed random numbers ($0 \le r_i \le 1$), we can sample the ϵ (x in the program) in the following way:

1. select i to be 1 or 2 according to the following ratio:

$$\texttt{BPAR} = \frac{\alpha_1}{\alpha_1 + \alpha_2}$$

   If $r_0 < \texttt{BPAR}$ then $i = 1$, otherwise if $r_0 \ge \texttt{BPAR}$ $i = 2$;

2. sample ϵ from $f_1(\epsilon)$. This can be performed by the following expressions:

$$\epsilon = \begin{cases} 0.5 - (0.5 - \epsilon_0)r_1^{\frac{1}{3}} & \text{when } i = 1 \\ \epsilon_0 + \left(\frac{1}{2} - \epsilon_0\right) r_1 & \text{when } i = 2 \end{cases}$$

3. calculate the rejection function $g_i(\epsilon)$. If $r_2 \le g_i(\epsilon)$, accept ϵ, otherwise return to step 1.

It should be mentioned that we need a step just after sampling ϵ in the step 2, because the cross-section formula becomes negative at large δ and this imposes an upper limit for δ;

$$\delta_{max} = \exp\left[\frac{42.24 - F(Z)}{8.368}\right] - 0.952$$

If we get a δ value using the sampled ϵ such that $\delta > \delta_{max}$, we have to start again from the step 1. After the successful sampling of ϵ, GPAIRG generates the polar angles of the electron with respect to an axis defined along the direction of the parent photon. The electron and the positron are assumed to have a symmetric angular distribution. The energy-angle distribution is given by Tsai [13, 14] as following:

$$\frac{d\sigma}{dpd\Omega} \quad = \quad \frac{2\alpha^2 e^2}{\pi k m^4}\left\{ \left[\frac{2x(1 - x)}{(1 + l)^2} - \frac{12lx(1 - x)}{(1 + l)^4}\right](Z^2 + Z) \right.$$

$$\left. + \left[\frac{2x^2 - 2x + 1}{(1 + l)^2} + \frac{4lx(1 - x)}{(1 + l)^4}\right]\left[X - 2Z^2 f((\alpha Z)^2)\right]\right\}$$

where k is the photon energy, p and E are the momentum and the energy of the electron of the e^+e^--pair, $x = E/k$ and $l = E^2\theta^2/m^2$. This distribution is quite complicated to sample and, furthermore, considered

as function of the variable $u = E\theta/m$, it shows a very weak dependence on Z, E, k, $x = E/k$. Thus, the distribution can be approximated by a function

$$f(u) = C\left(ue^{-au} + due^{-3au}\right) \tag{4}$$

where

$$
\begin{aligned}
C &= \frac{9a^2}{9+d} \\
a &= 0.625 \\
d &= 27.0
\end{aligned}
$$

The sampling of the function $f(u)$ can be done in the following way (r_i are uniformly distributed random numbers in [0,1]):

1. choose between ue^{-au} and due^{-3au}, with relative probability given by $9/(9+d)$ and $d/(9+d)$ respectively; if $r_1 < 9/(9+d)$ then $b = a$, else $b = 3a$;

2. sample ue^{-bu}, $u = -(\ln r_2 + \ln r_3)/b$.

The azimuthal angle, ϕ, is generated isotropically.

This information together with the momentum conservation is used to calculate the momentum vectors of both decay products and to transform them to the GEANT coordinate system. The choice of which particle in the pair is the electron/positron is made randomly.

2.3 Restrictions

1. Effects due to the breakdown of Born approximation at low energies are ignored (but the Coulomb correction is now included):

2. as suggested by Ford and Nelson [15], for very low energy photons ($E \leq 2.1 MeV$) the electron energy is approximated by sampling from a uniform distribution over the interval $m \rightarrow 1/(2E)$. The reason for this suggestion is that the sampling method used in EGS and in the earlier GEANT versions becomes progressively more inefficient as the pair threshold is approached. This is not true for the sampling method outlined above (the efficiency of the method practically does not depend on the photon energy), but we have chosen to keep this approximation;

3. target materials composed of compounds or mixtures are treated identically to chemical elements (this is not the case when computing the mean free path!) using the effective atomic number computed in the routine GSMIXT. It can be shown that the error of this type of treatment is small and can be neglected;

4. the differential cross-section implicitly accounts for pair production in both nuclear and atomic electron fields. However, triplet production is not generated, and the recoil momentum of the target nucleus/electron is assumed to be zero.

Total cross-section for Compton scattering

1 Subroutines

CALL **GCOMPI**

GCOMPI calculates the total cross-section for Compton scattering. It tabulates the mean free path, $\lambda = \frac{1}{\Sigma}$ (in cm), as a function of the medium and of the energy (see JMATE data structure). The energy binning is set within the array ELOW (common /GCMULO/) in the routine GPHYSI. GCOMPI is called at initialisation time by GPHYSI.

2 Method

The mean free path, λ, for a photon to interact via Compton scattering is given by

$$\lambda = \frac{1}{\Sigma} = \frac{A}{N_{Av}\rho}\frac{1}{\sigma(Z,E)}$$

where:

N_{Av} Avogadro's number

Z, A atomic and mass number of the medium

ρ density of the medium

σ total cross-section per atom for Compton scattering

E energy of the photon.

For the total cross-section an empirical cross-section formula is used which reproduces the cross-section data rather well down to 10 keV:

$$\sigma(Z,E) = Z\left[P_1(Z)\frac{\log(1+2X)}{X} + \frac{P_2(Z) + P_3(Z)X + P_4(Z)X^2}{1 + aX + bX^2 + cX^3}\right] \text{ barn atom}^{-1}$$

where

$$
\begin{aligned}
m &= \text{electron mass}\\
X &= \frac{E}{m}\\
P_i(Z) &= D_i + E_i Z + F_i Z^2
\end{aligned}
$$

The values of the parameters are put in the DATA statement within the routine GCOMPI. The fit was made over 511 data points chosen between:

$$1 \le Z \le 100 \quad ; \quad 10 \text{ keV} \le E \le 100 \text{ GeV}$$

The accuracy of the fit is estimated to be:

$$\frac{\Delta\sigma}{\sigma} = \begin{cases} \approx 10\% & \text{for E } \simeq 10 \text{ keV} - 20 \text{ keV} \\ \le 5 - 6\% & \text{for E } > 20 \text{ keV} \end{cases}$$

Simulation of Compton scattering

1 Subroutines

CALL **GCOMP**

GCOMP generates the Compton scattering of a photon on an atomic electron. It uses the random number techniques of Butcher and Messell [10] to sample the scattered photon energy according to the Klein-Nishina formula [16].

The interaction produces one electron, which is put in the /GCKING/ common block for further tracking. Tracking of the scattered photon will continue, with direction and energy changed by the interaction. All input/output information is through GEANT common blocks.

Input: via COMMON /GCTRACK/

Output: via COMMONs /GCTRAK/ and /GCKING/

Compton scattering is selected in GEANT by the input data record COMP. When Compton scattering is selected, GCOMP is called automatically from the GEANT photon tracking routine GTGAMA.

2 Method

For a complete account of the Monte Carlo methods used the interested user is referred to the publications of Butcher and Messel [10], Messel and Crawford [17] and Ford and Nelson [12]. Only the basic formalism is outlined here.

The quantum mechanical Klein-Nishina differential cross-section is:

$$\Phi(E, E') = \frac{X_0 n \pi r_0^2 m_e}{E^2} \left[\frac{1}{\epsilon} + \epsilon \right] \left[1 - \frac{\epsilon \sin^2 \theta}{1 + \epsilon^2} \right]$$

where, E = energy of the incident photon
E' = energy of the scattered photon
ϵ = E'/E
m_e = electron mass
n = electron density
r_0 = classical electron radius
X_0 = radiation length

Assuming an elastic collision, the scattering angle θ is defined by the Compton formula:

$$E' = E \frac{m_e}{m_e + E(1 - \cos \theta)}$$

Using the combined "composition and rejection" Monte Carlo methods described in chapter PHYS211, we

may set:

$$f(\epsilon) = \left[\frac{1}{\epsilon} + \epsilon\right] = \sum_{i=1}^{2} \alpha_i f_i(E) \quad \text{for} \qquad \epsilon_0 > \epsilon > 1$$

$$g(\epsilon) = \left[1 - \frac{\epsilon \sin^2 \theta}{1 + \epsilon^2}\right] \qquad \text{rejection function}$$

$$\alpha_1 = \ln(1/\epsilon_0) \qquad\qquad \alpha_2 = \frac{1}{2}(1 - \epsilon_0^2)$$

$$f_1(\epsilon) = \frac{1}{\epsilon \ln(1/\epsilon_0)} \qquad\qquad f_2(\epsilon) = \frac{2\epsilon}{1 - \epsilon_0^2}$$

The value of ϵ corresponding to the minimum photon energy (backward scattering) is given by:

$$\epsilon_0 = \frac{1}{1 + 2E/m_e}$$

Given a set of random numbers r_i uniformly distributed in [0,1], the sampling procedure for ϵ is the following:

1. decide which element of the $f(\epsilon)$ distribution to sample from. Let $\alpha_T = (\alpha_1 + \alpha_2)r_0$. If $\alpha_1 \geq \alpha_T$ select $f_1(\epsilon)$, otherwise select $f_2(\epsilon)$;

2. sample ϵ from the distributions corresponding to f_1 or f_2. For f_1 this is simply achieved by:

$$\epsilon = \epsilon_0 e^{\alpha_1 r_1}$$

For f_2, we change variables and use:

$$\epsilon' = \begin{cases} \max(r_2, r_3) & \text{for} \quad E/m \geq (E/m + 1)r_4 \\ r_5 & \text{for all other cases} \end{cases}$$

Then, $\epsilon = \epsilon_0 + (1 - \epsilon_0)\epsilon'$;

3. calculate $\sin^2 \theta = \max(0, t(2 - t))$ where $t = m_e(1 - \epsilon)/E'$

4. test the rejection function, if $r_6 \leq g(\epsilon)$ accept ϵ, otherwise return to step 1.

After the successful sampling of ϵ, GCOMP generates the polar angles of the scattered photon with respect to the direction of the parent photon. The azimuthal angle, ϕ, is generated isotropically and θ is as defined above. The momentum vector of the scattered photon is then calculated according to kinematic considerations. Both vectors are then transformed into the GEANT coordinate system.

3 Restriction

The differential cross-section is only valid for those collisions in which the energy of the recoil electron is large compared with its binding energy (which is ignored). However, as pointed out by Rossi [18], this has a negligible effect because of the small number of recoil electrons produced at very low energies.

Total cross-section for photoelectric effect

1   Subroutines

CALL **GPHINI**

GPHINI steers initialisation of the constants. It calls GHPRIN for initialisation of the atom decay rates, GHSLIN to initialise atomic shell potentials and ionisation energies and GPHXIN for the initialisation of the cross-section constants. It is called by GPHOTI.

CALL **GPHRIN**

Initialisation of the atom decay rates. The routine is called by GPHINI.

CALL **GSHLIN**

Initialisation of the atomic shell potentials and ionisation energies. GSHLIN is called by GPHINI.

CALL **GPHXIN**

Initialisation of the cross-section constants for elements with $Z \leq 100$. It is called by GPHINI.

CALL **GPHXSI**

GPHXSI is called by GPHYSI for every tracking medium. It calculates the cross-section coefficients. The results of the calculations are stored in the photoelectric effect constants bank created by this routine.

CALL **GFSHDC**

GFSHDC calls GFRDT, GNRDT and GFSDPR for the probabilities of atomic state transitions and the transition energies and stores them in the ZEBRA bank. It is called by GPHXSI.

CALL **GFSHLS**

GFSHLS returns the shell potentials in eV for an atom. It is called by GFSHDC.

CALL **GFRDT**

GFRDT returns probability distribution and energies of the atomic radiative transitions. It is called by GFSHDC.

CALL **GNFRDT**

GNFRDT returns probability distribution and energies of the non-radiative atomic transitions. It is called by GFSHDC.

CALL **GFSDPR**

GFSDPR returns probability of the shell radiative decay. It is called by GFSHDC.

CALL **GPHOTI**

GPHOTI calculates the total cross-section for the photoelectric effect. It tabulates the mean free path, $\lambda = 1/\Sigma$ (in cm), as a function of the medium and the energy. If $Z \leq 100$ then it calls the function GPHSG1 for the total cross-section. Otherwise GPHSIG function is used. GPHOTI is called at initialisation time by GPHYSI.

VALUE   =   **GPHSG1**   (EGAM)

GPHSG1 calculates the total cross-section for photoelectric effect. It is called by GPHOTI for $Z \leq 100$.

VALUE   =   **GPHSIG**   (Z,EGAM)

GPHSIG calculates the total cross-section for the photoelectric effect of a photon with energy EGAM in material with atomic number $Z > 100$. It is called by GPHOTI.

2 Method

2.1 Materials with $Z \leq 100$

For media with $Z \leq 100$ we use SANDIA parametrisation [19]. The cross-section for elements was fitted with a linear combination of reciprocal powers of the photon energy E_γ (E_γ in keV). The fits were performed in different intervals j of the photon energy. In such an interval the cross-section reads as:

$$\mu_{ij} = \frac{C_{1,ij}}{E_\gamma} + \frac{C_{2,ij}}{E_\gamma^2} + \frac{C_{3,ij}}{E_\gamma^3} + \frac{C_{4,ij}}{E_\gamma^4} \quad (cm^2 g^{-1}) \tag{1}$$

with j changing from 1 to m_i, where m_i is the number of fitting intervals used for element i.

For the composites or mixtures of N elements the cross-section for j^{th} interval is calculated as:

$$\mu_j = \sum_{k=1}^{N} f_k \mu_{j,k} \tag{2}$$

where f_k is the fraction by mass of kth element in the material. Substituting (1) into (2) one finds that the cross-section coefficients can be calculated as:

$$C_{i,total} = \sum_{k=1}^{N} f_k C_{i,jk} \tag{3}$$

for i from 1 to 4. The macroscopic cross-section is calculated as follows:

$$\Sigma = \rho\mu \quad (cm^{-1}) \tag{4}$$

where ρ is the medium density.

As follows from (3) each compound is decomposed to its components which should coincide with chemical elements. If this is not the case i.e. a component has a non-integer atomic number Z_x and is created by a call to GSMATE then the cross-section constants are calculated using two elements with $Z_1 = integer(Z_x)$ and $Z_2 = Z_1 + 1$ applying the weights $w_1 = Z_2 - Z_x$ and $w_2 = Z_x - Z_1$ respectively.

2.2 Materials with $Z > 100$

Originally the parametrisation described below was developed for the elements with the atomic number Z between 5 and 100. Lacking more accurate data and assuming that there are no dramatic changes of the cross-section behaviour this method (i.e. GPHSIG function) is used for $Z > 100$.

The macroscopic cross-section for an element is given by

$$\Sigma = \frac{N\rho\sigma(Z, E_\gamma)}{A} \quad (cm^{-1}) \tag{5}$$

and for a compound or a mixture

$$\Sigma = \frac{N\rho \sum_i \sigma(Z_i, E_\gamma)}{\sum_i n_i A_i} = N\rho \sum_i \frac{p_i}{A_i}\sigma(Z_i, E_\gamma) \quad (cm^{-1}) \tag{6}$$

where

N	Avogadro's number
$Z(Z_i)$	atomic number (of ith component) of the medium
$A(A_i)$	atomic mass (of ith component) of the medium
ρ	density
σ	cross-section
n_i	proportion by number of the ith element in the material ($n_i = Wp_i/A_i$ where p_i is the corresponding proportion by weight and W is the molecular weight).

The binding energy of the inner shells has been parameterised as:

$$E_i(Z) = Z^2(A_i + B_iZ + C_iZ^2 + D_iZ^3) \quad \text{MeV} \tag{7}$$

where, $i = K, L_I, L_{II}$ and the constants A_i, B_i, C_i and D_i are tabulated below.

	A	B	C	D
K	$0.66644 \cdot 10^{-5}$	$0.22077 \cdot 10^{-6}$	$-0.32552 \cdot 10^{-8}$	$0.18199 \cdot 10^{-10}$
L_I	$-0.29179 \cdot 10^{-6}$	$0.87983 \cdot 10^{-7}$	$-0.12589 \cdot 10^{-8}$	$0.69602 \cdot 10^{-11}$
L_{II}	$-0.68606 \cdot 10^{-6}$	$0.10078 \cdot 10^{-6}$	$-0.14496 \cdot 10^{-8}$	$0.78809 \cdot 10^{-11}$

The photoelectric effect total cross-section has been parameterised as:

$$\sigma(Z, E) = Z^\alpha X^\beta \begin{cases} \begin{aligned} p_1/Z \;+\;\; & p_2X + p_3 + p_4Z + p_5/X + p_6Z^2 \\ + \;\; & p_7Z/X + p_8/X^2 + p_9Z^3 \\ + \;\; & p_{10}Z^2/X + p_{11}Z/X^2 + p_{12}/X^3 \end{aligned} & \text{if} \quad E > E_k(Z) \\ p_{13}/Z + p_{14}X + p_{15} & \text{if} \quad E_{L_I} < E \le E_k(Z) \\ p_{16}/Z + p_{17}X + p_{18} & \text{if} \quad E_{L_{II}} < E \le E_{L_I} \\ p_{19} & \text{if} \quad 10\,keV \le E \le E_{L_{II}} \end{cases} \tag{8}$$

where X is the ratio of the electron mass to the incident photon energy and σ is expressed in barns/atom. The fit was made over 301 data points chosen between $5 \le Z \le 100$ and $10\,keV \le E \le 50\,MeV$. The values of the parameters are put in a `DATA` statement within the function `GPHSIG` which computes the formula (8). The accuracy of the fit is estimated to be

$$\frac{\Delta}{\sigma} \le \begin{cases} 25\% & \text{near to the peaks} \\ 10\% & \text{elsewhere.} \end{cases}$$

3 Photoelectric effect Bank

The banks connected to the photoelectric effect are created during initialisation for each tracking medium. `PHXS` bank (data area) The total cross-section values are stored in `PHOT` bank in energy bins set within the array `ELOW` (common `CGMULO`). This bank is pointed by `JPHOT` link. The first structural link of `PHOT` supports the `PHXS` bank. For each energy interval of the cross-section we store the upper limit of the interval and four constants of equation (3). For each chemical element used to build the medium a `PHFN` bank is created. This bank, pointed by a structural link of the `PHXS` bank, contains the data needed for the photoelectric effect final state simulation. All data word are of the Fortran REAL type. The descriptions of the `PHXS` and `PHFN` banks are given below.

Word #	Description
1	`NZ`-number of chemical elements of the medium
2 → `NZ`+1	atomic numbers of the elements
`NZ`+2 → 2*`NZ`+1	not used at present
2*`NZ`+2 → 3*`NZ`+1	weights of the cross-section constants
3*`NZ`+2	`NIT`-number of the cross-section intervals
3*`NZ`+3 → 1+3*`NZ`+1+5*`NIT`	the total cross-section constants

PHFN bank (data area)

Word #	Description
1	`NIE`-number of intervals for an element
2 → `NIE`*5+1	the element cross-section constants
`NIE`*5+2	number of shells used. At present always 4
`NIE`*5+3 → `NIE`*5+6	binding energies of K, L_I, L_{II} and L_{III} shells
`NIE`*5+7 → `NIE`*5+10	probability of the radiative shell decay
`NIE`*5+11	pointer to the radiative decays of K shell `KRD`
`NIE`*5+12	pointer to the radiative decays of L_I shell `L1RD`
`NIE`*5+13	pointer to the radiative decays of L_{II} shell `L2RD`
`NIE`*5+14	pointer to the radiative decays of L_{III} `L3RD`
`NIE`*5+15	pointer to the non-radiative decays of K shell `KNRD`
`NIE`*5+16	pointer to the non-radiative decays of L_I shell `L1NRD`
`NIE`*5+17	pointer to the non-radiative decays of L_{II} shell `L2NRD`
`NIE`*5+18	pointer to the non-radiative decays of L_{III} shell `L3NRD`
`KRD`	number of K shell radiative decay modes `NRDK`
`KRD`+1 → `KRD`+1+`NRDK`	K shell decay mode probability
`KRD`+1+`NRDK` → `KRD`+1+2*`NRDK`	K shell transition energies
`L1RD`	number of L_I shell radiative decay modes `NRDL1`
`L1RD`+1 → `L1RD`+1+`NRDL1`	L_I shell decay mode probability
`L1RD`+1+`NRDL1` → `L1RD`+1+2*`NRDL1`	L_I shell transition energies
`L2RD`	number of L_I shell radiative decay modes `NRDL2`
`L2RD`+1 → `L2RD`+1+`NRDL2`	L_{II} shell decay mode probability
`L2RD`+1+`NRDL2` → `L2RD`+1+2*`NRDL2`	L_{II} shell transition energies
`L3RD`	number of L_I shell radiative decay modes `NRDL3`
`L3RD`+1 → `L3RD`+1+`NRDK`	L_{III} shell decay mode probability
`L3RD`+1+`NRDL3` → `L3RD`+1+2*`NRDL3`	L_{III} shell transition energies
`KNRD`	number of K shell radiative decay modes `RDK` = 1
`KNRD`+1 → `KNRD`+1+`RDK`	K shell decay mode probability
`KNRD`+1+`RDK` → `KNRD`+1+2*`RDK`	K shell transition energies
`L1NRD`	number of L_I shell radiative decay modes `RDL1` = 1
`L1NRD`+1 → `L1RD`+1+`RDL1`	L_I shell decay mode probability
`L1NRD`+1+`RDL1` → `L1RD`+1+2*`RDL1`	L_I shell transition energies
`L2NRD`	number of L_I shell radiative decay modes `RDL2` = 1
`L2NRD`+1 → `L2RD`+1+`NRDK`	L_{II} shell decay mode probability

Word #   Description

`L2NRD+1+RDL2 → L2RD+1+2*RDL2` L_{II} shell transition energies

`L3NRD`   number of L_I shell radiative decay modes `RDL3 = 1`

`L3NRD+1 → L3RD+1+RDL3` L_{III} shell decay mode probability

`L3NRD+1+RDL3 → L3RD+1+2*NRDL3` L_{III} shell transition energies

Simulation of photoelectric Effect

1   Subroutines

```
  CALL GPHOT   GPHOT
```

simulates the photoelectric effect. It uses the following input and output:

Input　　via common GCTRAK
Output　　via common GCKING

It calls the functions GPHSG1, GPHSGP, GAVRL2 and GAVRL3 for the cross-section and the functions GHPHAK, GHPHAL1, GHPHAL2, GPHAL3 for the cosine distribution of the photoelectron. GPHOT is called by the tracking routine GTGAMA, if, and when, the photon reaches its interaction point.

```
  VALUE = GAVRL2  (GAMAL2,BETAL2,X)
```

GAVRL2 calculates approximation of the cross-section for the photoelectric effect from L_{II} shell. GAMAL2, BETAL2 are the Lorentz gamma and beta factors of the emitted photoelectron and $X = m_e / E_\gamma$ where m_e is the electron mass and E_γ is the incident radiation energy. GAVRL2 is called by GHPOT.

```
  VALUE = GAVRL3  (GAMAL3,BETAL3,X)
```

GAVRL3 calculates approximation of the cross-section for the photoelectric effect from L_{III} shell. GAMAL3, BETAL3 are the Lorentz gamma and beta factors of the emitted photoelectron and $X = m_e / E_\gamma$ where m_e is the electron mass and E_γ is the incident radiation energy. GAVRL3 is called by GPHOT.

```
  VALUE = GPHAK  (BETAK)
```

```
  VALUE = GPHAL1  (BETAL1)
```

GPHAK and its entry point GPHAL1 poll the cosine distribution (w.r.t. the incident photon direction) of the photoelectron emitted from K or L_I shell, respectively. They are called by GPHOT.

```
  VALUE = GPHAL2  (BETAL2)
```

GPHAL2 polls the cosine distribution (w.r.t. the incident photon direction) of the photoelectron emitted from L_{II} shell.

```
  VALUE = GPHAL3  (BETAL3)
```

GPHAL3 polls the cosine distribution (w.r.t. the incident photon direction) of the photoelectron emitted from L_{III} shell. It is called by GPHOT.

```
  VALUE = GPHSGP  (EGAM)
```

GPHSGP calculates the photoelectric effect total cross-section for a particular atom of a mixture taking into account weights. It is called by GPHOT for $Z \leq 100$.

2 Method

If the energy of the radiation incident on an atom is E_γ, then the quanta can be absorbed if $E_\gamma > E_{shell}$. The photoelectron is emitted with total energy:

$$E_{photoelectron} = E_\gamma - E_{shell} + m_e. \tag{1}$$

In the above equation it is assumed that the atom has infinite mass. One should note that there exists a correction term (see [20] and references therein) which becomes more and more important with increasing E_γ [21] [22] [23].

2.1 Probability of Interaction with an Atom

Probability of the interaction with an atom is calculated taking into account partial cross-sections of atoms of a mixture or a compound.

2.2 Probability of Interaction with a Shell

To calculate the probability of the interaction with a particular shell we use the jump ratios defined as:

$$J_{shell} = \frac{\sigma(E_{shell} + \delta E)}{\sigma(E_{shell} - \delta E)} \tag{2}$$

where $\delta E \to 0$. In addition we assume that the jump ratio is also valid away from the edges.
From (2) it follows that the probability p_{shell} to interact with a shell is:

$$p_{shell} = 1 - \frac{1}{J_{shell}} \tag{3}$$

We use the following parametrisation of the jump ratios for K and L_I shells [24]:

$$J_K = \frac{125}{Z} + 3.5 \tag{4}$$

$$J_{L_I} = 1.2 \tag{5}$$

For the L_{II} and L_{III} shells we adopt approximation of the formulae calculated by Gavrila [25]:

$$\sigma_{L_{II}} = \gamma\beta\frac{m_e}{E_\gamma}\left\{\gamma^3 - 5\gamma^2 + 24\gamma - 16 - (\gamma^2 + 3\gamma - 8)\frac{\log(\gamma(1+\beta))}{\gamma\beta}\right\} \tag{6}$$

and

$$\sigma_{L_{III}} = \gamma\beta\frac{m_e}{E_\gamma}\left\{4\gamma^3 - 6\gamma^2 + 5\gamma + 3 - (\gamma^2 - 3\gamma + 4)\frac{\log(\gamma(1+\beta))}{\gamma\beta}\right\} \tag{7}$$

where

γ, β are the emitted photoelectron Lorentz gamma and beta factors;
E_γ is the incident radiation energy;
m_e is the electron mass.
Below an example of the shell interaction probability calculations for $E_\gamma > E_K$ is given.
If

$$\Sigma_{II,III} = \sigma_{L_{II}} + \sigma_{L_{III}}$$
$$r_{L_{II}} = \frac{\sigma_{L_{II}}}{\Sigma_{II,III}}$$
$$r_{L_{III}} = \frac{\sigma_{L_{III}}}{\Sigma_{II,III}}$$

then from (3) one can find that

$$p_K = 1 - \frac{1}{J_K}$$

$$p_{L_1} = (1 - p_K) \cdot \left(1 - \frac{1}{J_{L_1}}\right)$$

$$p_{L_{II}} = (1 - p_K - p_{L_I}) \cdot r_{L_{II}}$$

$$p_{L_{III}} = (1 - p_K - p_{L_I}) \cdot r_{L_{III}}$$

After simple calculations one obtains the probability distribution function which is used to select the shell.

2.3 Angular distributions of photoelectrons

The angular distributions of photoelectrons should be calculated using the partial wave analysis for the outgoing electron. Since this method is very time consuming we use approximations of the angular distributions calculated by F. von Sauter [26] [27] (K shell) and Gavrila [28] [25] (K and L shells). We use the cross-section which is correct only to zero order in αZ. This approximation foresees zero scattering amplitude in the direction of incident photon while experimentally the cross-section at 0 angle is non-vanishing [29]. If

$$X = 1 - \beta \cos \Theta$$

then for K and L_I shells we use:

$$\frac{d\sigma_{K,L_I}}{d(\cos \Theta)} \sim \frac{\sin^2 \Theta}{X^4} \left\{ 1 + \frac{1}{2}\gamma(\gamma - 1)(\gamma - 2) \right\} \tag{8}$$

and for L_{II} and L_{III} shells we have:

$$\frac{d\sigma_{L_{II}}}{d(\cos \Theta)} \sim \frac{(\gamma^2 - 1)^{\frac{1}{2}}}{\gamma^5(\gamma - 1)^5} \left\{ \frac{\gamma(3\gamma + 1)}{2X^4} - \frac{\gamma^2(9\gamma^2 + 30\gamma - 7)}{8X^3} \right.$$
$$+ \frac{\gamma^3(\gamma^3 + 6\gamma^2 + 11\gamma - 2)}{4X^2} - \frac{\gamma^4(\gamma - 1)(\gamma + 7)}{8X} \tag{9}$$
$$\left. + \sin^2 \Theta \left(\frac{(\gamma + 1)}{X^5} - \frac{\gamma(\gamma + 1)}{X^4} - \frac{\gamma^2(3\gamma + 1)(\gamma^2 - 1)}{X^3} \right) \right\}$$

$$\frac{d\sigma_{L_{III}}}{d(\cos \Theta)} \sim \frac{(\gamma^2 - 1)^{\frac{1}{2}}}{\gamma^5(\gamma - 1)^5} \left\{ -\frac{\gamma(3\gamma - 1)}{2X^4} + \frac{\gamma^2(3\gamma^2 - 1)}{X^3} \right.$$
$$\frac{\gamma^3(\gamma^3 - 3\gamma^2 + 2\gamma + 1)}{X^3} - \frac{\gamma^4(\gamma - 2)(\gamma - 1)}{2X} \tag{10}$$
$$\left. + \sin^2 \Theta \left(\frac{(\gamma + 1)}{X^5} - \frac{\gamma(\gamma + 1)(3\gamma - 1)}{X^4} + \frac{\gamma^2(\gamma^2 - 1)}{X^3} \right) \right\}$$

The azimuthal angle distribution is uniform.

2.4 Final State

After the photoelectron emission the atom is left in excited state. The excitation energy equal to the binding energy E_i of the shell in which the interaction took place. Subsequently the atom emits a fluorescent photon or Auger or Coster-Kronig electron. The selection of radiative or non-radiative transition is based on compilation by Krause [30].
The Auger or Coster-Kronig transitions are represented by the most probable line for a given vacancy [31]. The emitted electron energy E_e is

$$E_e = E_i - (E_j + E_k) \tag{11}$$

where E_i, E_j, E_k are the subshell binding energies and $E_j > E_k$.

In case of fluorescence we use transition rates of Scofield [32]. We use only those transitions for which the occurrence probability is not less than 1%. The fluorescent photon is emitted with energy E_γ

$$E_\gamma = E_i - E_j \tag{12}$$

for transition between the subshells i and j.

In addition to the above, to fulfill the energy conservation law, emission of an additional photon is simulated. For non-radiative transitions its energy is E_k (see formula 11). In case of fluorescent transition this photon has energy E_j (see equation 12). The angular distribution of the emitted particle is isotropic.

Photon-induced fission on heavy materials

1   Subroutines

CALL **GPFISI**

`GPFISI` computes and stores in the appropriate bank (see `JMATE` data structure) the value of the photo-fission cross sections as a function of the energy for all the material for which this process is activated and with $230 \leq A \leq 240$. It is called during initialisation by `GPHYSI`.

CALL **GPFIS**

`GPFIS` is called by the tracking routine `GTGAMA` to generate the final state of a photon-induced fission.

2   Method

This set of routines generates the photon-induced fission in the nuclei of heavy materials. The code is a straight translation into the `GEANT` style of the corresponding code from the `GHEISHA` Monte Carlo program.

The information contained in this chapter is mainly taken from the `GHEISHA` manual to which the user is referred [1]. In fissionable elements the inelastic reaction of photons may be accompanied by the fission of the nucleus. This channel is taken into account only when the nuclear mass is between 230 and 240. The fission cross-section for uranium is tabulated, and for other elements the parameterisation of the A-dependence at 3 MeV neutron energy is used:

$$\sigma_f(3MeV) = -67.0 + 38.7\, Z^{4/3} A$$

which implies that the fission may occur only for $Z \geq 90$. The fission products are generated in an approximate way. The giant resonance effect is included here as nuclear photoabsorbtion. The photo-fission is activated by the data record `PFIS`. Secondaries coming from the interaction of the virtual photon with the nucleus will be in the `GEANT` temporary stack. If `IPFIS=2` the secondary particles will not be generated and the energy of the photon will be summed to `DESTEP`. A table with the photo-fission cross-sections as a function of the energy is put in a bank at initialization time for all the materials with A bigger than 230. See material bank structure for details.

Total cross-section for Rayleigh scattering

1   Subroutines

```
CALL GRAYLI
```

`GRAYLI` computes the mean free path, λ, for Rayleigh scattering as a function of the medium and of the energy. It evaluates also an integral of atomic form factors which is used in the routine `GRAYL` (see [PHYS251]) to sample the scattering angles. `GRAYLI` is called during initialization by `GPHYSI`.

2   Method

2.1   Total cross-section

An empirical cross-section is used to produce the total cross-section data [12, 33]:

$$\sigma_c (Z, E) = aE^3 + bE^2 + cE + d \qquad \text{barn/atom} \tag{1}$$

The values of the coefficients are stored in the `DATA` statement within the routine `GRAYLI`. For each element the fit was obtained over 27 experimental values of the total coherent cross-section. The accuracy of the fit is estimated to be about $\Delta\sigma/\sigma \approx 10\%$, but it is better for most of the elements.

2.2   The atomic form factors

Different empirical formulae are used to produce the atomic form factor F(Z,E) data [34]. For $Z = 1 - 3, 91 - 99$ the empirical expression is:

$$F(Z, E) = a_1 E^7 + b_1 E^6 + c_1 E^5 + d_1 E^4 + e_1 E^3 + f_1 E^2 + g_1 E + h_1 \tag{2}$$

for Z=100 the formula used is:

$$F(Z, E) = a_2 E^5 + b_2 E^4 + c_2 E^3 + d_2 E^2 + e_2 E + f_2 \tag{3}$$

for the other elements F is calculated as:

$$F(Z, E) = \begin{cases} a_3 E^3 + b_3 E^2 + c_3 E + d_3 & \text{if } E \leq E_c \\ a_4 E^3 + b_4 E^2 + c_4 E + d_4 & \text{if } E > E_c \end{cases} \tag{4}$$

The value of the energy E_c depends on Z and it is set in the array `ELIM`. The values of the coefficients are stored in the `DATA` statement in the routine `GRAYLI`. For each element the fits were performed over 97 tabulated values of the form factors. The accuracy of the fit is estimated to about $\Delta\sigma/\sigma = 10\%$ for $E \leq 1$ MeV for most of the elements. The integral over the atomic form factors $A(E_i)$ is defined as follows:

$$A(E_i) = 2 \int_0^{E_i} |F_T(E)|^2 E \, dE = \int_0^{E_i} |F_T(E)|^2 dE^2 \tag{5}$$

where $F_T(E)$ is the total atomic form factor which is function of the energy E.

Simulation of Rayleigh scattering

> CALL **GRAYL**

GRAYL generates Rayleigh scattering of a photon using the random-number composition and rejection technique to sample the momentum of the scattered photon and the scattering angle, according to the form-factor distribution. In this reaction no new particles are generated and the kinematical quantities of the scattered photon replace the original ones in the /GCTRAK/ common block.

Activation of the Rayleigh scattering is done via the FFREAD data record RAYL. If this process is activated, **GRAYL** is called by **GTGAMA** when a Rayleigh scattering occurs.

1 Method

The Rayleigh differential cross section as a function of q^2 is given by [35]:

$$\frac{d\sigma_R(q^2)}{d\Omega} = \frac{\pi r_0^2}{k^2}\left(\frac{1+\mu^2}{2}\right)|F_T(q)|^2 \tag{1}$$

where:

r_0 electron radius

k incident wave vector

$q = 2k\sin\dfrac{\theta}{2}$ momentum of scattered photon (θ is the scattering angle)

$\mu = cos\theta \quad = 1 - \dfrac{q^2}{2k^2}$

$F_T(q)$ molecular form factor

Under the assumption that the atoms of a molecule are completely independent, $|F_T(q)|^2$ is given by:

$$|F_T(q)|^2 = \sum_{i=1}^{N} \frac{W_i}{A_i}|F_i(q_i, Z_i)|^2\,\sigma_{c_i}(Z_i, E) \tag{2}$$

where the index i runs on the N atoms in the molecule and:

W_i proportion by weight

Z_i, A_i atomic number and weight

F_i form factor

σ_{c_i} total atomic cross section for coherent scattering

Using the combined composition and rejection sampling method described in GPAIRG ([PHYS211]) we may set:

$$f(q) = \sum_{i=1}^{N} \alpha_i f_i(q)\,g_i(q) = \sum_{i=1}^{N} A(q_i^2)\frac{|F_T(q)|^2}{A(q_n^2)}\left(\frac{1+\mu^2}{2}\right) \tag{3}$$

where:

n number of energy bins

q_i momentum of the photon with energy E_i of the ith bin

q_n upper limit for the momentum of the scattered photon

α_i $A\left(q_i^2\right)$

$f_i(q)$ $\dfrac{|F_T(q)|^2}{A\left(q_n^2\right)}$

$g_i(q) \quad = \dfrac{1+\mu^2}{2}$ rejection function.

Therefore, for given values of the random numbers r_1 and r_2, `GRAYL` samples the momentum of the scattered photon and the scattering angle θ via the following steps:

1. sample $A\left(q^2\right) = r_1 A\left(q_n^2\right)$

2. find the $(q_{i-1}, q_i]$ interval which gives $A\left(q_{i-1}^2\right) \leq A\left(q^2\right) \leq A\left(q_i^2\right)$

3. calculate the linear extrapolation:

$$q = q_{i-1} + \left(A\left(q^2\right) - A\left(q_{i-1}^2\right)\right) \frac{q_i - q_{i-1}}{A\left(q_i^2\right) - A\left(q_{i-1}^2\right)} \tag{4}$$

4. calculate $\mu = cos\theta = 1 - q^2/(2k^2)$

5. calculate $g_i(q) = (1 + \mu^2)/2$

6. if $g_i(q) > r_2$ the event is accepted, otherwise go back to 1.

Čerenkov photons

Čerenkov photons are produced when a charged particle traverses a dielectric material.

1 Physics processes for optical photons

A photon is called optical when its wavelength is much greater than the typical atomic spacing, for instance when $\lambda \geq 10nm$ which corresponds to an energy $E \leq 100eV$. Production of an optical photon in a HEP detector is primarily due to:

1. Čerenkov effect;

2. Scintillation;

3. Fluorescence.

Fluorescence is taken into account in `GEANT` in the context of the photoelectric effect (`[PHYS230]`, `[PHYS231]`), but only above the energy cut `CUTGAM`. Scintillation is not yet simulated by `GEANT`.

Optical photons undergo three kinds of interactions:

1. Elastic (Rayleigh) scattering;

2. Absorption;

3. Medium boundary interactions.

1.1 Elastic scattering

For optical photons elastic scattering is usually unimportant. For $\lambda = .200\mu m$ we have $\sigma_{Rayleigh} \approx .2b$ for N_2 or O_2 which gives a mean free path of ≈ 1.7 km in air and ≈ 1 m in quartz. An important exception to this is found in aerogel, which is used as a Čerenkov radiator for some special applications. Because of the spectral properties of this material, Rayleigh scattering is extremely strong and this limits its usefulness as a RICH radiator. At present, elastic scattering of optical photons is not simulated in `GEANT`.

1.2 Absorption

Absorption is important for optical photons because it determines the lower λ limit in the *window* of transparency of the radiator. Absorption competes with photo-ionisation in producing the signal in the detector, so it must be treated properly in the tracking of optical photons.

1.3 Medium boundary effects

When a photon arrives at the boundary of a dielectric medium, its behaviour depends on the nature of the two materials which join at that boundary:

- Case dielectric $\rightarrow$ dielectric.
  The photon can be transmitted (refracted ray) or reflected (reflected ray). In case where the photon can only be reflected, total internal reflection takes place.

- Case dielectric → metal.

   The photon can be absorbed by the metal or reflected back into the dielectric. If the photon is absorbed it can be detected according to the photoelectron efficiency of the metal.

- Case dielectric → black material.

   A *black* material is a tracking medium for which the user has not defined any optical property. In this case the photon is immediately absorbed undetected.

2   Photon polarisation

The photon polarisation is defined as a two component vector normal to the direction of the photon:

$$
\begin{pmatrix} a_1 e^{i\phi_1} \\ a_2 e^{i\phi_2} \end{pmatrix} = e^{\phi_o} \begin{pmatrix} a_1 e^{i\phi_c} \\ a_2 e^{-i\phi_c} \end{pmatrix}
$$

where $\phi_c = (\phi_1 - \phi_2)/2$ is called circularity and $\phi_o = (\phi_1 + \phi_2)/2$ is called overall phase. Circularity gives the left- or right-polarisation characteristic of the photon. RICH materials usually do not distinguish between the two polarisations and photons produced by the Čerenkov effect are linearly polarised, that is $\phi_c = 0$. The circularity of the photon is ignored by GEANT.

The overall phase is important in determining interference effects between coherent waves. These are important only in layers of thickness comparable with the wavelength, such as interference filters on mirrors. The effects of such coatings can be accounted for by the empirical reflectivity factor for the surface, and do not require a microscopic simulation. GEANT does not keep track of the overall phase.

Vector polarisation is described by the polarisation angle $\tan \psi = a_2/a_1$. Reflection/transmission probabilities are sensitive to the state of linear polarisation, so this has to be taken into account. One parameter is sufficient to describe vector polarisation, but to avoid too many trigonometrical transformations, a unit vector perpendicular to the direction of the photon is used in GEANT.

The polarisation vectors are stored in a special track structure which is lifted at the link LQ(JSTACK-1) when the first Čerenkov photon is stored in the stack.

3   Method

3.1   Generation of the photons

For the formulas contained in this chapter, please see [36]. Let n be the refractive index of the dielectric material acting as a radiator ($n = c/c'$ where c' is the group velocity of light in the material: it follows that $1 \leq n$). In a dispersive material n is an increasing function of the photon momentum p_γ, $dn/dp \geq 0$. A particle travelling with speed $\beta = v/c$ will emit photons at an angle θ with respect to its direction, where θ is given by the relation:

$$
\cos \theta = \frac{1}{\beta n}
$$

from which follows the limitation for the momentum of the emitted photons:

$$
n(p_\gamma^{min}) = \frac{1}{\beta}
$$

Additionally, the photons must be within the window of transparency of the radiator. All the photons will be contained in a cone of opening $\cos \theta_{max} = 1/(\beta n(p_\gamma^{max}))$.

The average number of photons produced is given by the relations (Gaussian units):

$$
dN = \frac{2\pi z^2 e^2}{\hbar c} \sin^2 \theta \frac{d\nu}{c} dx = \frac{2\pi z^2 e^2}{\hbar c} \left(1 - \cos^2 \theta\right) \frac{d\nu}{c} dx = \frac{2\pi z^2 e^2}{\hbar c} \left(1 - \frac{1}{n^2 \beta^2}\right) \frac{d\nu}{c} dx =
$$

$$= \frac{z^2 e^2}{\hbar^2 c^2} \left(1 - \frac{1}{n^2 \beta^2} \right) dp_\gamma \; dx \approx 370 z^2 \frac{photons}{cm\;eV} \left(1 - \frac{1}{n^2 \beta^2} \right) dp_\gamma \; dx$$

and

$$\frac{dN}{dx} \approx 370 z^2 \int_{p_\gamma^{min}}^{p_\gamma^{max}} dp_\gamma \left(1 - \frac{1}{n^2 \beta^2} \right) = 370 z^2 \left(p_\gamma^{max} - p_\gamma^{min} - \frac{1}{\beta^2} \int_{p_\gamma^{min}}^{p_\gamma^{max}} dp_\gamma \frac{1}{n(p_\gamma)^2} \right)$$

The number of photons produced is calculated from a Poissonian distribution with average value $\bar{n} = $ STEP dN/dx. The momentum distribution of the photon is then sampled from the density function:

$$f(p_\gamma) = \left(1 - \frac{1}{n^2 (p_\gamma) \beta^2} \right)$$

3.2 Tracking of the photons

Čerenkov photons are tracked in the routine GTCKOV. These particles are subject to *in flight* absorption (process LABS, number 101) and *boundary action* (process LREF, number 102, see above). As explained above, the status of the photon is defined by 2 vectors, the photon momentum ($\vec{p} = \hbar \vec{k}$) and photon polarisation ($\vec{e}$). By convention the direction of the polarisation vector is that of the electric field. Let also $\vec{u}$ be the normal to the material boundary at the point of intersection, pointing out of the material which the photon is leaving and toward the one which the photon is entering. The behaviour of a photon at the surface boundary is determined by three quantities:

1. refraction or reflection angle, this represents the kinematics of the effect;

2. amplitude of the reflected and refracted waves, this is the dynamics of the effect;

3. probability of the photon to be refracted or reflected, this is the quantum mechanical effect which we have to take into account if we want to describe the photon as a particle and not as a wave;

As said above, we distinguish three kinds of boundary action, dielectric $\rightarrow$ black material, dielectric $\rightarrow$ metal, dielectric $\rightarrow$ dielectric. The first case is trivial, in the sense that the photon is immediately absorbed and it goes undetected.

To determine the behaviour of the photon at the boundary, we will at first treat it as an homogeneous monochromatic plane wave:

$$\vec{E} = \vec{E}_0 e^{i \vec{k} \cdot \vec{x} - i \omega t}$$
$$\vec{B} = \sqrt{\mu \epsilon} \frac{\vec{k} \times \vec{E}}{k}$$

Case dielectric $\rightarrow$ dielectric

In the classical description the incoming wave splits into a reflected wave (quantities with a double prime) and a refracted wave (quantities with a single prime). Our problem is solved if we find the following quantities:

$$\vec{E'} = \vec{E'}_0 e^{i \vec{k'} \cdot \vec{x} - i \omega t}$$
$$\vec{E''} = \vec{E''}_0 e^{i \vec{k''} \cdot \vec{x} - i \omega t}$$

For the wave numbers the following relations hold:

$$\vert \vec{k} \vert \;=\; \vert \vec{k}'' \vert = k = \frac{\omega}{c}\sqrt{\mu\epsilon}$$

$$\vert \vec{k}' \vert \;=\; k' = \frac{\omega}{c}\sqrt{\mu'\epsilon'}$$

Where the speed of the wave in the medium is $v = c/\sqrt{\mu\epsilon}$ and the quantity $n = c/v = \sqrt{\mu\epsilon}$ is called *refractive index* of the medium. The condition that the three waves, refracted, reflected and incident have the same phase at the surface of the medium, gives us the well known Fresnel law:

$$\big(\vec{k}\cdot\vec{x}\big)_{surf} \;=\; \big(\vec{k}'\cdot\vec{x}\big)_{surf} = \big(\vec{k}''\cdot\vec{x}\big)_{surf}$$

$$k\sin i \;=\; k'\sin r = k''\sin r'$$

where i, r, r' are, respectively, the angle of the incident, refracted and reflected ray with the normal to the surface. From this formula the well known condition emerges:

$$i \;=\; r'$$

$$\frac{\sin i}{\sin r} \;=\; \sqrt{\frac{\mu'\epsilon'}{\mu\epsilon}} = \frac{n'}{n}$$

The dynamic properties of the wave at the boundary are derived from Maxwell's equations which impose the continuity of the normal components of $\vec{D}$ and $\vec{B}$ and of the tangential components of $\vec{E}$ and $\vec{H}$ at the surface boundary. The resulting ratios between the amplitudes of the the generated waves with respect to the incoming one are expressed in the two following cases:

1. a plane wave with the electric field (polarisation vector) perpendicular to the plane defined by the photon direction and the normal to the boundary:

$$\frac{E_0'}{E_0} \;=\; \frac{2n\cos i}{n\cos i + \frac{\mu}{\mu'}n'\cos r} = \frac{2n\cos i}{n\cos i + n'\cos r}$$

$$\frac{E_0''}{E_0} \;=\; \frac{n\cos i - \frac{\mu}{\mu'}n'\cos r}{n\cos i + \frac{\mu}{\mu'}n'\cos r} = \frac{n\cos i - n'\cos r}{n\cos i + n'\cos r}$$

where we suppose, as it is legitimate for visible or near-visible light, that $\mu/\mu' \approx 1$;

2. a plane wave with the electric field parallel to the above surface:

$$\frac{E_0'}{E_0} \;=\; \frac{2n\cos i}{\frac{\mu}{\mu'}n'\cos i + n\cos r} = \frac{2n\cos i}{n'\cos i + n\cos r}$$

$$\frac{E_0''}{E_0} \;=\; \frac{\frac{\mu}{\mu'}n'\cos i - n\cos r}{\frac{\mu}{\mu'}n'\cos i + n\cos r} = \frac{n'\cos i - n\cos r}{n'\cos i + n\cos r}$$

whith the same approximation as above.

We note that in case of photon perpendicular to the surface, the following relations hold:

$$\frac{E_0'}{E_0} = \frac{2n}{n'+n} \qquad\qquad \frac{E_0''}{E_0} = \frac{n'-n}{n'+n}$$

where the sign convention for the *parallel* field has been adopted. This means that if $n' > n$ there is a phase inversion for the reflected wave.

Any incoming wave can be separated into one piece polarised parallel to the plane and one polarised perpendicular, and the two components treated accordingly.

To mantain the particle description of the photon, the probability to have a *refracted* (mechanism 107) or *reflected* (mechanism 106) photon must be calculated. The constraint is that the number of photons be conserved, and this can be imposed via the conservation of the energy flux at the boundary, as the number of photons is proportional to the energy. The energy current is given by the expression:

$$\vec{S} = \frac{1}{2}\frac{c}{4\pi}\sqrt{\mu\epsilon}\,\vec{E}\times\vec{H}^* = \frac{c}{8\pi}\sqrt{\frac{\epsilon}{\mu}}E_0^2\,\hat{k}$$

and the energy balance on a unit area of the boundary requires that:

$$\begin{aligned}
\vec{S}\cdot\vec{u} &= \vec{S}'\cdot\vec{u} - \vec{S}''\cdot\vec{u} \\
S\cos i &= S'\cos r + S''\cos i \\
\frac{c}{8\pi}\frac{1}{\mu}nE_0^2\cos i &= \frac{c}{8\pi}\frac{1}{\mu'}n'E_0'^2\cos r + \frac{c}{8\pi}\frac{1}{\mu}nE_0''^2\cos i
\end{aligned}$$

If we set again $\mu/\mu' \approx 1$, then the transmission probability for the photon will be:

$$T = \left(\frac{E_0'}{E_0}\right)^2 \frac{n'\cos r}{n\cos i}$$

and the corresponding probability to be reflected will be $R = 1 - T$.

In case of reflection the relation between the incoming photon $(\vec{k},\vec{e})$, the refracted one $(\vec{k}',\vec{e}\,')$ and the reflected one $(\vec{k}'',\vec{e}\,'')$ is given by the following relations:

$$\begin{aligned}
\vec{q} &= \vec{k}\times\vec{u} \\
e_\parallel &= \frac{\vec{e}\cdot\vec{u}}{|q|} \\
e_\perp &= \frac{\vec{e}\cdot\vec{q}}{|q|} \\
e_\parallel' &= e_\parallel\frac{2n\cos i}{n'\cos i + n\cos r} \\
e_\perp' &= e_\perp\frac{2n\cos i}{n\cos i + n'\cos r} \\
e_\parallel'' &= \frac{n'}{n}e_\parallel' - e_\parallel \\
e_\perp'' &= e_\perp' - e_\perp
\end{aligned}$$

After transmission or reflection of the photon, the polarisation vector is renormalised to 1. In the case where $\sin r = n\,\sin i/n' > 1$ then there cannot be a refracted wave, and in this case we have a total internal reflection according to the following formulas:

$$\begin{aligned}
\vec{k}'' &= \vec{k} - 2(\vec{k}\cdot\vec{u})\vec{u} \\
\vec{e}\,'' &= -\vec{e} + 2(\vec{e}\cdot\vec{u})\vec{u}
\end{aligned}$$

Case dielectric → metal

In this case the photon cannot be transmitted. So the probability for the photon to be absorbed by the metal is estimated according to the table provided by the user. If the photon is not absorbed, it is reflected.

3.3 Surface effects

In the case where the surface between two bodies is perfectly polished, then the normal provided by the program is the normal to the surface defined by the body boundary. This is indicated by the the value `POLISH= 1` as returned by the `GUPLSH` function. When the value returned is < 1, then a random point is generated in a sphere of radius $1-$`POLISH`, and the corresponding vector is added to the normal. This new normal is accepted if the reflected wave is still inside the original volume.

4 Subroutines

> CALL **GSCKOV** (ITMED, NPCKOV, PPCKOV, ABSCO, EFFIC, RINDEX)

`ITMED`	(`INTEGER`) tracking medium for which the optical properties are to be defined;
`NPCKOV`	(`INTEGER`) number of bins in the tables;
`PPCKOV`	(`REAL`) array containing `NPCKOV` values of the photon momentum in GeV;
`ABSCO`	(`REAL`) array containing `NPCKOV` values of the absorption length in centimeters in case of dielectric and of the boundary layer absorption probabilities in case of a metal;
`EFFIC`	(`REAL`) array containing `NPCKOV` values of the detection efficiency;
`RINDEX`	(`REAL`) array containing `NPCKOV` values of the refractive index for a dielectric, if `RINDEX(1) = 0` the material is a metal;

This routine declares a tracking medium either as a radiator or as a metal and stores the tables provided by the user. In the case of a metal the `RINDEX` array does not need to be of length `NPCKOV`, as long as it is set to 0. The user should call this routine if he wants to use Čerenkov photons. Please note that for the moment only `BOX`es, `TUBE`s, `CONE`s, `SPHE`res, `PCON`s, `PGON`s, `TRD2`s and `TRAP`s can be assigned optical properties due to the current limitations of the `GGPERP` routine described below.

> CALL **GLISUR** (XO, X1, MEDIO, MEDI1, U, PDOTU, IERR)

`XO`	(`REAL`) current position (`XO(1)=`x, `XO(2)=`y, `XO(3)=`z) and direction (`XO(4)=`p_x, `XO(5)=`p_y, `XO(6)=`p_z) of the photon at the boundary of a volume;
`X1`	(`REAL`) position (`X1(1)=x`, `X1(2)=y`, `X1(3)=z`) beyond the boundary of the current volume, just inside the new volume along the direction of the photon;
`MEDIO`	(`INTEGER`) index of the current tracking medium;
`MEDI1`	(`INTEGER`) index of the tracking medium into which the photon is entering;
`U`	(`REAL`) array of three elements containing the normal to the surface to which the photon is approaching;
`PDOTU`	(`REAL`) $- \cos \theta$ where θ is the angle between the direction of the photon and the normal to the surface;
`IERR`	(`INTEGER`) error flag, `GGPERP` could not determine the normal to the surface if `IERR` $\neq 0$;

This routine simulates the surface profile between two media as seen by an approaching particle with coordinate and direction given by `XO`. The surface is identified by the arguments `MEDIO` and `MEDI1` which are the tracking medium indices of the region in which the track is presently and the one which it approaches, respectively. The input vector `X1` contains the coordinates of a point on the other side of the boundary from `XO` and lying in within medium `MEDI1`. The result is a unit vector `U` normal to the surface of reflection at `XO` and pointing into the medium from which the track is approaching.

The quality of the surface finish is given by the parameter returned by the user function `GUPLSH` (see below).

```
    VALUE  =  GUPLSH   (MEDIO, MEDI1)
```

This function must be supplied by the user. It returns a value between 0 and 1 which decsribes the quality of the surface finish between `MEDIO` and `MEDI1`. The value 0 means maximum roughness with effective plane of reflection distributed as $\cos \alpha$ where α is the angle between the unit normal to the *effective* plane of reflection and the normal to the nominal medium boundary at `X0`. The value 1 means perfect smoothness. In between the surface is modelled as a bell-shaped distribution in α with limits given by:

$$\sin \alpha = \pm(1 - \texttt{GUPLSH})$$

At the interface between two media the routine is called to evaluate the surface. The default version in `GEANT` returns 1, i.e. a perfectly polished surface is assumed. When `GUPLSH = 0` the distribution of the normal to the surface is $\approx \cos \theta$.

MEDIO   (`INTEGER`) index of the current tracking medium;
MEDI1   (`INTEGER`) index of the tracking medium into which the photon is entering;

```
    CALL  GGCKOV
```

This routine handles the generation of Čerenkov photons and is called from `GTHADR`, `GTMUON` and `GTELEC` in radiative materials for which the optical characteristics have been defined via the routine `GSCKOV`.

```
    CALL  GSKPHO   (IPHO)
```

IPHO   (`INTEGER`) number of the Čerenkov photon to store on the stack to be tracked. If `IPHO = 0` all the generated photons will be put on the stack to be tracked.

This routines takes the Čerenkov photon `IPHO` generated during the current step and stores it in the stack for subsequent tracking. This routine performs for Čerenkov photons the same function that the `GSKING` routine performs for all the other particles. The generated photons are stored in the common `/GCKIN2/` (`[ZZZZ010]`).

```
    CALL  GTCKOV
```

This routine is called to track Čerenkov photons. The user routine `GUSTEP` is called at every step of tracking. When `ISTOP = 2` the photon has been absorbed. If `DESTEP` $\neq 0$ then the photon has been detected.

```
    CALL  GGPERP   (X, U, IERR)
```

X   (`REAL`) array of dimension 3 containing the current position of the track in the MARS;
U   (`REAL`) array of dimension 3 containing on exit the normal to the surface of the current volume at the point `X`;
IERR   (`INTEGER`) error flag: if `IERR` $\neq 0$ `GGPERP` failed to find the normal to the surface of the current volume.

This routine solves the general problem of calculating the unit vector normal to the surface of the current volume at the point X. The result is returned in the array `U`. X is assumed to be outside the current volume and near a boundary (within `EPSIL`). The current volume is indicated by the common `/GCVOLU/`. U points from inside to outside in that neighbourhood. If X is within `EPSIL` of more than one boundary (i.e. in a corner) an arbitrary choice is made. If X is inside the current volume or if the current volume is not handled by the routine, the routine returns with `IERR=1`, otherwise `IERR=0`. At the moment the routine only handles `BOX`es, `TUBE`s, `SPHE`res and `CONE`s.

5 Processes involving Čerenkov photons

The process of generating a Čerenkov photon is called `CKOV` and corresponds to the process value 105 (variable `LMEC` in common `/GCTRAK/`). This process is activated only in a radiator defined via the routine `GSCKOV`.

The process of photon absorption (name `LABS`, code 101) is controlled by the `LABS FFREAD` data record. By default the process is activated for all the materials for which optical properties have been defined.

The action taken at the boundary is identified by the process name `LREF`, code 102.

At a boundary a photon can be either reflected (name `REFL`, code 106) or refracted (name `REFR`, code 107).

Gaussian multiple scattering

1   Subroutines

```
CALL GMGAUS  (BETA2,DIN*)
```

BETA2   (REAL) β^2;

DIN   (REAL) array of 3 containing the direction of the scattered particle with respect to the incoming direction.

This routine is called by `GTELEC`, `GTHADR`, `GTMUON` and `GTHION` via `GMULTS` when the variable `IMULS`, controlled by the data record `MULS` is equal to 3.

2   Method

2.1   Approximations in use

A charged particle traversing a medium is deflected by many scatters, mostly at small angle. These scatters are due to the interaction with the Coulomb field of the nuclei, and to a lesser degree, to the electron field, hence the name of Coulomb scattering. For hadronic projectiles, however, the strong interaction contributes to multiple scattering. Multiple scattering is well described by Molière theory [37]. Molière multiple scattering theory is used by default in `GEANT` (see [PHYS325]). We define $\theta_0 = \theta_{plane}^{rms} = \theta_{space}^{rms}/\sqrt{2}$ as the r.m.s. of the angle between the directions projected on a plane of a particle before and after traversing a thickness t of absorber. In this case a simple form for the multiple Coulomb scattering of singly charged particles which is widely used is:

$$\theta_0 \approx \frac{15\,MeV}{E\beta^2}\sqrt{\frac{t}{X_0}}$$

where X_0 is the radiation length of the absorber. This form was proposed by [38], [39]. It can introduce large errors because it ignores significant dependences from pathlength and Z. To compensate for this, a similar formula was proposed [40], [41]:

$$\theta_0 \approx \frac{14.1\,MeV}{E\beta^2}\sqrt{\frac{t}{X_0}}\left[1 + 0.038\log\left(\frac{t}{X_0}\right)\right] \tag{1}$$

A form taking into account the β and z dependence of the particle has been proposed by [42]:

$$\theta_0 = \frac{S_2}{E\beta^2}\sqrt{\frac{t}{X_0}}\left[1 + \epsilon\log_{10}\left(\frac{tZ_{inc}^2}{X_0\beta^2}\right)\right] \tag{2}$$

The problem with the formulae (1) and (2) is that if the distance t in the absorber is travelled in two steps $t = t_1 + t_2$, the r.m.s. angle $\theta_0(t) = \theta_0(t_1 + t_2) \neq \sqrt{\theta_0^2(t_1) + \theta_0^2(t_2)}$, limiting their use in a MonteCarlo like `GEANT`.

Much of the difficulty in approximating multiple Coulomb scattering in terms of the radiation length is that the number of radiation lengths is a poor measure of the scattering. A better expression, which is used in GEANT has been proposed by [42]:

$$\theta_0^2 = \frac{\chi_c^2}{1 + F^2} \left[\frac{1 + \nu}{\nu} \log(1 + \nu) - 1 \right] \qquad (3)$$

where

$$\nu = \frac{\Omega_0}{2(1 - F)}$$

$$F = \text{fraction of the tracks in the sample}$$

$$\Omega_0 = \frac{\chi_c^2}{1.167\chi_\alpha^2} \quad \text{is the mean number of scatters}$$

χ_c^2 and χ_α^2 are parameters of the Molière theory, for which the reader is invited to see [PHYS325], and $1.167 \approx \exp(2\gamma - 1)$ where γ is the Euler's constant $= 0.57721\ldots$. This form, which is the result of empirical fits, is derived from the screened Rutherford cross section, which has the form $2\chi_\alpha^2/(\chi_\alpha^2 + \theta_0^2)$. For F anywhere from 0.9 to 0.995 this expression represents Molière scattering to better than 2% for $10 < \Omega_0 < 10^8$, which covers singly charged relativistic particles ($\beta \approx 1$) in the range $10^{-3} < t/X_0 < 100$. In GEANT we have adopted the values of $F = 0.98$ and $\Omega_0 = 40,000$ scatters, obtaining the following formula:

$$\theta_0 = 2.557\chi_{cc} \frac{\sqrt{t}}{E\beta^2}$$

where χ_{cc} is another parameter of the Molière theory for which the reader is referred to [PHYS325]. This algorithm is implemented by the routine GMGAUS.

Molière scattering

1　Subroutines

1.1　Initialisation

```
CALL GMULOF
```

`GMULOF` calculates the table of maximum steps corresponding to the energies in the array `ELOW` for electrons and muons. It is called during initialisation by `GPHYSI`. For hadrons and ions the computation is performed during tracking in the routines `GTHADR` and `GTHION`.

```
CALL GMOLI  (AC,ZC,WMAT,NLM,DENS,OMC*,CHC*)
```

`AC`　　　　　`REAL` array of dimenstion `NLM` containing the mass numbers;
`ZC`　　　　　`REAL` array of dimenstion `NLM` containing the atomic numbers;
`WMAT`　　　`REAL` array containing the proportions by weight of the component of a mixture/compound. `1` in case of a single component;
`NLM`　　　　`INTEGER` number of the elements in the mixture/compound;
`DENS`　　　`REAL` density in g cm^{-3};
`OMC`　　　　`REAL` b_c constant of Molière theory;
`CHC`　　　　`REAL` χ_{cc} constant of Molière theory.

`GMOLI` calculates the two material-dependent constants (`OMC` and `CHC`). These are needed during initialisation by `GMULOF` and during tracking to sample the scattering angle, as explained below. It is called at initialisation time by the routine `GPROBI` which initialises some material constants and computes the probabilities for various processes.

1.2　Sampling of the multiple scattering angle

```
CALL GMULTS
```

`GMULTS` is the steering routine for the sampling of the multiple scattering angle when the variable `IMULTS` in common `/GCPHYS/` is 1 or 2. This variable can be controlled by the `MULT` data record. The routine decides if the material-dependent constant `OMC` computed by `GMOLI` during initialisation has to be corrected due to its dependence on β and Z_{inc}, and selects Molière theory (`GMOLIE`) or single Coulomb scattering (`GMCOUL`). It updates the direction of the particle in the array `VECT` (COMMON `GCTRAK`). It is called by the tracking routines `GTELEC`, `GTHADR`, `GTHION` and `GTMUON`.

```
CALL GMOLIO  (AC,ZC,WMAT,NLM,DENS,BETA2,CHARG2,OMC*)
```

`BETA2`　　　`REAL` β^2 of the particle;
`CHARG2`　　`REAL` charge squared of the particle in electron charge unit (Z_{inc}^2 in the following).

All the other arguments are routine `GMOLI`. `GMOLIO` re-evaluates the material-dependent constant `OMC`. It is called by `GMULTS`, if needed.

```
CALL GMOLIE  (OMEGA,BETA2,DIN*)
```

OMEGA	REAL Ω_0 of the Molière theory;
BETA2	REAL β^2 of the particle;
DIN	REAL array of dimension 3 containing the new direction cosines with respect to the original direction of the particle.

GMOLIE samples the multiple scattering angle according to Molière theory, as explained in the next section. It is called by the multiple scattering steering routine GMULTS,

```
   CALL GMOL4   (Y*,X,VAL,ARG,EPS,IER*)
```

Y	REAL value of the interpolated function;
X	REAL value at which the function should be interpolated;
VAL	REAL array of four values of the function to interpolate;
ARG	REAL array of four values of the argument of the function to which the values contained in VAL correspond;
EPS	REAL required precision for the interpolation;
IER	INTEGER error flag;

GMOL4 inverts the integral of Molière distribution function using four-points continued-fraction interpolation. It is called by GMOLIE.

2   Method

2.1   Introduction

When traversing ordinary matter, elementary particles undergo deflection from their originary trajectory due to the interaction with the atoms. This effect is rather large for charged particles, which are deflected by the electric field of nuclei and electrons via a large number of small elastic *collisions*. To simulate precisely the transport of particles in matter, it is important to provide a precise description of this effect. Considerable effort has gone over the years into the formulation of a theory of Coulomb multiple scattering. In GEANT we follow the theory originally formulated by Molière [43] [44] and then elaborated by Bethe [37]. A review of this theory can be found in [45].

It should be noted that this is not the only theory which describes multiple Coulomb scattering, and a thorough analysis of the problem has been performed by Goudsmit and Saunderson [46] [47].

A complete account of the Molière theory is outside the scope of this manual. For more information the interested reader could refer to the works cited above and to the EGS4 manual [15], from which the notation used in the present chapter has been derived.

The principal limitations of Molière theory are the following:

1. the angular deflection is *small*. Effectively this constraint provides the upper limit for the step-size;

2. the theory is a *multiple scattering* theory; that is, many atomic collisions participate in causing the incident particle to be deflected. In some implementations, this constraints provides a lower limit on the step size. In GEANT, when the number of scatters is below the limit of applicability of Molière single Coulomb scatterings are simulated, so that there is no effective minimum step size below which multiple scattering is *switched off*;

3. the theory applies only in semi-infinite homogeneous media. This constraint calls for a very careful handling of particles near to a medium's boundary;

4. there is no energy loss built into the theory. This again introduces the necessity to take small steps;

In Molière theory corrected for finite angle scattering ($\sin\theta \neq \theta$) as described by Bethe [37, 45], the angular distribution is given by:

$$f(\theta)\,\theta d\theta \quad = \quad \sqrt{\frac{\sin\theta}{\theta}}\, f_r(\eta)\,\eta d\eta, \tag{1}$$

where for $f_r(\eta)$ we use the first three terms of Bethe's expansion:

$$f_r(\eta) = f_r^{(0)}(\eta) + f_r^{(1)}(\eta)B^{-1} + f_r^{(2)}(\eta)B^{-2}$$

$$\eta = \frac{\theta}{\chi_c \sqrt{B}}$$

(2)

η is called the *reduced angle*.

2.2 Calculation of the reduced angle

In formula (2) above χ_c the *critical scattering angle* defined as:

$$\chi_c^2 = \frac{4\pi e^4 Z_s \rho N_{Av} Z_{inc}^2 t}{W c^2 p^2 \beta^2} = \chi_{cc}^2 Z_{inc}^2 \frac{t}{E^2 \beta^4}$$

(3)

with

Z_{inc}	incident particle charge
Z_s	defined below
N_{Av}	Avogadro's number
ρ	density
W	$\sum_{i=1}^{N} n_i A_i$ molecular weight
E	particle energy in MeV
r_0	$e^2/(mc^2)$ classical electron radius
t	total path length in the scatterer (and not its thickness).

The variable χ_c is factorised into two parts. The first part, χ_{cc}, is a constant of the medium for a given incident particle. The second part depends on the incident particle energy and on the path length in the medium.

$$\chi_{cc}^2 = \frac{4\pi e^4 Z_s \rho N_{Av}}{W} = \frac{4\pi c^4 r_0^2 m_e^2 Z_s \rho N_{Av}}{W} \approx (0.39612\,10^{-3})^2 Z_s \frac{\rho}{W} \left[\, GeV^2\ cm^{-1} \right]$$

(4)

The variable `CHC` or `CHCMOL` stored in `Q(JPROB+25)` corresponds to χ_{cc}. B is defined by the equation

$$B - \ln B = \ln \Omega_0,$$

(5)

where Ω_0 can be interpreted as the number of collisions in the step:

$$\Omega_0 = \frac{\chi_c^2}{e^{2\gamma-1}\chi_\alpha^2} = b_c Z_{inc}^2 \frac{t}{\beta^2}$$

(6)

Here γ is Euler's constant ($\gamma = 0.57721\ldots$) and χ_α the atomic electron screening angle. For a single element this is given by:

$$\chi_\alpha^2 = \left(\frac{\lambda_0}{2\pi r_{TF}}\right)^2 \left[1.13 + 3.76\left(\frac{\alpha Z Z_{inc}}{\beta}\right)^2\right]$$

where

$\dfrac{\lambda_0}{2\pi}$	$= $	$\hbar/p$ Compton wavelength of the electron
r_{TF}	$= $	$0.885 a_0 Z^{-\frac{1}{3}}$ Thomas-Fermi radius of the atom
a_0	$= $	$\dfrac{\hbar^2}{me^2}$ Bohr's radius
α	$= $	$1/137.035\ldots$ the fine-structure constant

so that we have

$$\chi_\alpha^2 = \frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2} Z^{\frac{2}{3}} \left[1 + 3.34 \left(\frac{\alpha Z Z_{inc}}{\beta} \right)^2 \right].$$

For a compound/mixture the following rule holds:

$$\ln(\chi_\alpha^2) = \frac{\sum_{i=1}^{N} n_i Z_i (Z_i + 1) \ln(\chi_{\alpha i}^2)}{\sum_{i=1}^{N} n_i Z_i (Z_i + 1)} = \frac{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \ln(\chi_{\alpha i}^2)}{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1)}$$

$$= \frac{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \ln \left\{ \frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2} Z_i^{\frac{2}{3}} \left[1 + 3.34 \left(\frac{\alpha Z_i Z_{inc}}{\beta} \right)^2 \right] \right\}}{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1)}$$

$$= \ln \left(\frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2} \right) - \frac{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \ln Z_i^{-\frac{2}{3}}}{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1)}$$

$$+ \frac{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \left[1 + 3.34 \left(\frac{\alpha Z_i Z_{inc}}{\beta} \right)^2 \right]}{\sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1)}$$

To understand the transformations in the above formulae, the following should be noted. Let n_i be the number of atoms of type i in a compound/mixture, that is the number of moles of element i in a mole of material, and p_i the proportion by weight of that element. We have the following relation:

$$p_i = \frac{n_i A_i}{\sum_{j=1}^{N} n_j A_j} \qquad \text{that is} \qquad n_i = \left(\sum_{j=1}^{N} n_j A_j \right) \frac{p_i}{A_i} = W \frac{p_i}{A_i}$$

so that we can simplify expressions in the following way:

$$\frac{\sum_{i=1}^{N} n_i \ldots}{W} = \sum_{i=1}^{N} (p_i / A_i) \ldots$$

If now we set

$$Z_s = \sum_{i=1}^{N} n_i Z_i (Z_i + 1) \qquad\qquad = W \sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \qquad = W Z_s'$$

$$Z_E = \sum_{i=1}^{N} n_i Z_i (Z_i + 1) \ln Z_i^{-2/3} \qquad = W \sum \frac{p_i}{A_i} Z_i (Z_i + 1) \ln Z_i^{-2/3} = W Z_E'$$

$$Z_x = \sum_{i=1}^{N} n_i Z_i (Z_i + 1) \ln \left[1 + 3.34 \left(\frac{\alpha Z_i Z_{inc}}{\beta} \right)^2 \right]$$

$$= W \sum_{i=1}^{N} \frac{p_i}{A_i} Z_i (Z_i + 1) \ln \left[1 + 3.34 \left(\frac{\alpha Z_i Z_{inc}}{\beta} \right)^2 \right] \qquad\qquad\qquad = W Z_x'$$

we can write:

$$\ln(\chi_\alpha^2) = \ln\left(\frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2}\right) + \frac{Z_x - Z_E}{Z_s}$$

$$\chi_\alpha^2 = \frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2} e^{(Z_x - Z_E)/Z_s} = \frac{m^2 e^4 1.13}{p^2 \hbar^2 (0.885)^2} e^{(Z'_x - Z'_E)/Z'_s}$$

and finally:

$$\Omega_0 = \frac{\chi_c^2}{e^{2\gamma - 1} \chi_\alpha^2}$$

$$= \frac{1}{1.167} \frac{4\pi e^4 Z_s \rho N_{Av} Z_{inc}^2 t}{W c^2 p^2 \beta^2} \frac{p^2 \hbar^2 (0.885)^2}{1.13 m^2 e^4} e^{-(Z'_x - Z'_E)/Z'_s}$$

$$= b_c Z_{inc}^2 \frac{t}{\beta^2}$$

$$b_c = \frac{4\pi N_{Av} \hbar^2}{m^2 c^2} \frac{(0.885)^2}{1.13 \times 1.167} \rho Z'_s e^{(Z'_E - Z'_x)/Z'_s} \approx 6702.33 \rho Z'_s e^{(Z'_E - Z'_x)/Z'_s}$$

The quantity b_c is calculated during initialisation by the routine `GMOLI` setting $\beta = 1$ and $Z_{inc} = 1$. This variable is called `OMC` or `OMCMOL` and it is stored in `Q(JPROB+21)`. It has, via the atomic electron screening angle χ_α^2, a small dependence on β and Z_{inc} in the term Z_x. The quantity $b_c \rho Z'_s$ is re-evaluated during tracking by the routine `GMOLIO`, called by `GMULTS`, only when necessary.

The dependence of Z_x on β and Z_{inc} is via a term of the form: $1 + 3.34 \left(\alpha Z Z_{inc} \beta^{-1}\right)^2$, so it is not necessary to recalculate it as long as $1 + 3.34 \left(\alpha Z Z_{inc} \beta^{-1}\right)^2 \approx 1 + 3.34 \left(\alpha Z\right)^2$ that is:

$$3.34 (Z\alpha)^2 \left[\left(\frac{Z_{inc}}{\beta}\right)^2 - 1\right] \ll 1 \qquad \Rightarrow \qquad Z^2 \frac{Z_{inc}^2 - \beta^2}{\beta^2} \ll 3.34\alpha^{-2} \approx 5500$$

$$Z^2 (Z_{inc}^2 - \beta^2) \le 50\beta^2$$

For mixtures/compounds this condition should be checked for every component and this would be unacceptable from the point of view of computer time. So we simply make the condition more restrictive multiplying the first term by the number of elements in the mixture/compound.

2.3 Sampling of the distribution function

The component distribution functions (2) are given by

$$f_r^{(0)}(\eta) = 2e^{-\eta^2} = 2D_0(1, 1, -\eta^2)$$

$$f_r^{(1)}(\eta) = 2D_1(2, 1, -\eta^2)$$

$$f_r^{(2)}(\eta) = D_2(3, 1, -\eta^2),$$

where $D_n(a, b, z) = d^n [\Gamma(a) M(a, b, z)]/da^n$, with $M(a, b, z)$ the Kummers hypergeometric function. Integrals of the functions $f_r^{(1)}$ and $f_r^{(2)}$ needed for the Monte Carlo can be written down directly in terms of the D functions

$$\int_\eta^\infty \eta f_r^{(1)} \eta d\eta = D_1(2, 1, -\eta^2) - D_1(1, 1, -\eta^2) - D_0(1, 1, -\eta^2)$$

$$\int_\eta^\infty \eta f_r^{(2)} \eta d\eta = \frac{1}{2} D_2(3, 1, -\eta^2) - D_2(2, 1, -\eta^2) - D_1(2, 1, -\eta^2)$$

We note that the first term is just the Gaussian part and it dominates for large B, that is, for large number of scatters, as it has to be expected. Recalling the definition of η in (2) we can say that the half-width of the Gaussian part of the Molière distribution is $\sigma^2 = \chi_c^2 B/2$. Routine `GMOLIE` performs the sampling of the Molière distribution via the following steps:

1. the value of B is calculated recursively. If we set $f(B) = B$ with $f(B) = \ln\Omega_0 + \ln B$ the relation used is $B_n = B_{n-1} + \Delta B = B_{n-1} + (f(B_{n-1}) - B_{n-1})/(1 - 1/B_{n-1})$. Convergence is assumed when $|\Delta B| \le 10^{-4}$.

2. a random number r_1 is sampled and a table of four values $F_r(\eta_i)$ is built with $i = j - 2, j - 1, j, j + 1$ and $F_r(\eta_j) \ge r_1$. F is the distribution function derived from (2):

$$
\begin{aligned}
F_r(\eta) &= \int_0^\eta f_r(t)\,dt = \int_0^\eta f_r^{(0)}(t) + f_r^{(1)}(t)B^{-1} + f_r^{(2)}(t)B^{-2}\,dt \\
&= \int_0^\eta f_r^{(0)}(t)\,dt + B^{-1}\int_0^\eta f_r^{(1)}(t)\,dt + B^{-2}\int_0^\eta f_r^{(2)}(t)\,dt \\
&= F_r^{(0)}(\eta) + B^{-1}F_r^{(1)}(\eta) + B^{-2}F_r^{(2)}(\eta)
\end{aligned}
$$

40 values of the functions $F_r^{(n)}$ are tabulated.

3. using a four-points continued-fraction interpolation method (`GMOL4`) a table of η_i^2 is interpolated using the values of r_1 and F tabulated in the previous step. This is similar to the inversion of the distribution function, but instead of obtaining directly the random variable, we interpolate a table of its squares. This provides a better fit to the inverse function;

4. the value of $\theta = \chi_c\sqrt{B\eta^2}$ is calculated;

5. a random number r_2 is extracted, and the rejection function $g(\theta) = \sqrt{\sin\theta/\theta}$ is computed. If $r_2 > g(\theta)$ resampling begins from step 2, otherwise the value is accepted.

The Molière distribution gives the space scattering angle. A similar expression may be written for the lateral displacement of the scattered particles. However, the problem of joint angle lateral displacement in the Molière approximation has not been solved, and, for small step size, lateral displacement is of second order and may be neglected. This introduces a problem when large step sizes are taken. The step size can be artificially limited via the use of the variable `STEMAX`, which is an argument to the routine `GSTMED`. For more information on this point the user is invited to consult chapter [`CONS200`].

3 Path and step length

3.1 Restrictions on the step length

Restrictions on the length of the step arise from:

1. the number of scatters $\Omega_0 \ge 20$ to stay within the multiple scattering regime. When $\Omega_0 < 20$, an appropriate number of *single* scatterings is used. See routine `GMCOUL` [`PHYS328`].

2. $\chi_c^2 B \le 1$ i.e. the width of the Gaussian part of the distribution should be less than one radian. This condition induces a maximum step length for the multiple scattering called t_{Bethe}. In order to find this value we write the limiting condition as $\chi_c^2(t_{Bethe})B(t_{Bethe}) = 1$, that is $B(t_{Bethe}) = 1/\chi_c^2(t_{Bethe})$. Now using equation (5) we take the exponential of both members $B(t_{Bethe})\Omega_0(t_{Bethe}) = \exp(1/\chi_c^2(t_{Bethe}))$. Dividing the two last equalities we obtain:

$$
\begin{aligned}
\Omega_0(t_{Bethe}) = \frac{b_c Z_{inc}^2}{\beta^2}t_{Bethe} &= \chi_c^2(t_{Bethe})\exp(1/\chi_c^2(t_{Bethe})) \\
&= \frac{\chi_{cc}^2 Z_{inc}^2 t_{Bethe}\,\exp\left[(E^2\beta^4)/(\chi_{cc}^2 Z_{inc}^2 t_{Bethe})\right]}{E^2\beta^4} \\
\exp\left[(E^2\beta^4)/(\chi_{cc}^2 Z_{inc}^2 t_{Bethe})\right] &= \frac{b_c E^2\beta^2}{\chi_{cc}^2} \\
t_{Bethe} &= \frac{E^2\beta^4}{\chi_{cc}^2\,Z_{inc}^2\,\ln\left[b_c E^2\beta^2/\chi_{cc}^2\right]}
\end{aligned}
$$

For electrons and muons this constraint on the step-length is tabulated at initialisation time in the routine `GMULOF` [PHYS201]. For hadrons this formula can be approximated as:

$$t_{Gauss} \approx \left(\frac{1}{14.1\ 10^{-3}} \frac{E^2 \beta}{Z_{inc}} \right)^2 X_0,$$

where E is in GeV and X_0 is the radiation length in centimeters and the formula has been taken from the Gaussian approximation to multiple scattering (see [PHYS320]). This condition is more restrictive, because it is equivalent to require that the width of the Gaussian part of the distribution be less than 0.5, but it has been found that the two conditions are numerically equivalent;

3. limitation due to the path length correction algorithm used (see below).

3.2   Path Length Correction

A path length correction may be applied in an approximate manner. We have from the Fermi-Eyges theory [15]

$$t = S + \frac{1}{2} \int_0^t \bar{\theta}^2 (\bar{t})\, dt \tag{7}$$

where

$\bar{\theta}^2 (\bar{t})$ the mean square angle of scattering;
S step size along a straight line;
t actual path length.

We have further:

$$\bar{\theta}^2 (\bar{t}) = \left(0.0212 \frac{Z_{inc}}{p\beta} \right)^2 \frac{t}{X_0} \tag{8}$$

X_0 is the radiation length. From (7) and (8) we get

$$S = t - Kt^2 \qquad \text{with} \qquad K = 1.12 \times 10^{-4} \frac{Z_{inc}^2}{p^2 \beta^2 X_0} \tag{9}$$

Equation (9) may be used to make the path length correction. Solving equation (9) with respect to t implies that, in order to obtain real solutions:

$$S \leq \frac{1}{4K} \qquad \text{i.e.} \qquad S \leq 2232 \frac{X_0 p^2 \beta^2}{Z_{inc}^2} \tag{10}$$

This condition provides an additional constraint to the maximum step length for multiple scattering (variable `TMXCOR` in routine `GMULOF`). The corrected step can be approximated as:

$$t \approx S(1 + KS) = S(1 + \text{CORR})$$

where `CORR` ≤ 0.25 due to condition (10).

Plural scattering

1   Subroutines

```
CALL GMCOUL  (OMEGA,DIN*)
```

OMEGA   (REAL) Ω_0 of the Molière theory;
DIN   (REAL) array of dimension 3 containing the direction of the scattered particle with respect to the incoming direction;

Generates single scatters in small angle approximation returning the new direction with respect to the old one. It is called by GMULTS when $\Omega_0 \leq 20$.

2   Method

In the Molière theory the average number of Coulomb scatters for a charged particle in a step is expressed by the parameter Ω_0 (see [PHYS325]). When $\Omega_0 \leq 20$, the Molière theory is not applicable any more, even if it has been noted [48] that it still gives reasonable results down to its *mathematical limit* $\Omega_0 = e$. The range $1 < \Omega_0 \leq 20$ is called the *plural scattering* regime. An interesting study of this regime can be found in [49].

In GEANT, when $\Omega_0 \leq 20$, a direct simulation method is used for the scattering angle. The number of scatters is distributed according to a Poissonian law with average $\Omega = k\Omega_0 = e^{2\gamma-1}\Omega_0 \approx 1.167\Omega_0$ with $\gamma = 0.57721\ldots$ Euler's constant. Using the customary notations for the probability distribution function for small angle ($\sin\theta \approx \theta$) single scattering, we can write:

$$f(\theta)\theta d\theta = \frac{d\sigma}{\theta d\theta}\frac{1}{\sigma}\theta d\theta \qquad (1)$$

where σ is the cross section for single elastic scattering. We use as cross section the one reported by Molière [43] [44]:

$$\frac{d\sigma}{\theta d\theta} = 2\pi\left(\frac{2Z\,Z_{inc}e^2}{pv}\right)^2\frac{1}{(\theta^2 + \chi_\alpha^2)^2}$$

This is the classical Rutherford cross section corrected by the screening angle χ_α. This angle is described by Molière as a correction to the Born approximation used to derive the quantum mechanical form of the Rutherford cross section. We have then:

$$\sigma = \int_0^\infty \frac{d\sigma}{\theta d\theta}\theta d\theta = 2\pi\left(\frac{2Z\,Z_{inc}e^2}{pv}\right)^2\int_0^\infty\frac{\theta d\theta}{(\theta^2+\chi_\alpha^2)^2} = \pi\left(\frac{2Z\,Z_{inc}e^2}{pv}\right)^2\frac{1}{\chi_\alpha^2}$$

and so equation (1) becomes:

$$f(\theta)\theta d\theta = \chi_\alpha^2\frac{2\theta d\theta}{(\theta^2+\chi_\alpha^2)^2} = \frac{2\Theta\,d\Theta}{(1+\Theta^2)^2}$$

where we have set $\Theta = \theta/\chi_\alpha$. To sample from this distribution we calculate the inverse of the distribution function:

$$\eta = \int_0^\Theta \frac{2t\,dt}{(1+t^2)^2} = 1 - \frac{1}{1+\Theta^2} \qquad \Rightarrow \qquad \Theta = \sqrt{\frac{1}{1-\eta} - 1}$$

where η is a number uniformly distributed between 0 and 1. If we observe that also $1 - \eta$ is uniformly distributed between 0 and 1 and we remember the definition of Θ, we obtain:

$$\theta = \sqrt{\chi_\alpha^2 \left(\frac{1}{\eta} - 1 \right)}$$

To calculate χ_α^2 we observe that:

$$\Omega_0 = \frac{\chi_c^2}{k\chi_\alpha^2}$$

$$\chi_\alpha^2 = \frac{\chi_c^2}{k\Omega_0} = \frac{\chi_{cc}^2 Z_{inc}^2 t / E^2 \beta^4}{k b_c Z_{inc}^2 t / \beta^2} = \frac{\chi_{cc}^2}{k b_c p^2 c^2}$$

where we have used the notations of [PHYS325] and $k = 1.167$.

Ionisation processes induced by $e^{\pm}$

1   Subroutines

CALL **GDRELA**

GDRELA initialises the ionisation energy loss tables for different materials for muons, electrons and positrons and other particles. The energy binning is set within the array ELOW (common /GCMULO/) in the routine GPHYSI. The tables are filled with the quantity dE/dx in GeV/cm (formula (4) below) which is valid for an element as well as a mixture or a compound. In the tables the dE/dx due to ionisation is summed with the energy loss coming from bremsstrahlung. For energy loss of electrons and positrons, it calls GDRELE using the following pointers:

  JMA = LQ(JMATE-I)   pointer to the Ith material
  JEL1 = LQ(JMA-1)   pointer for dE/dx for electrons
  JEL1+90   pointer for dE/dx for positron

GDRELA is called at initialisation time by GPHYSI.

CALL **GDRELE**   (EEL,CHARGE,JMA,DEDX)

GDRELE computes the ionisation energy loss (DEDX) for electrons (CHARGE = -1) and positrons (CHARGE = +1) with kinetic energy EEL in the material indicated by I in JMA = LQ(JMATE-I). It is called by the routine GDRELA.

CALL **GDRSGA**

CDRSGA calculates the total cross-section in all materials for delta rays for Möller ($e^- e^-$) and Bhabha ($e^- e^+$) scattering and for muons. It tabulates the mean free path, $\lambda = 1/\Sigma$ (in cm) as a function of the medium and the energy. The energy binning is set within the array ELOW (common /GCMULO/) in the routine GPHYSI. The following pointers are used (see JMATE data structure):

  JMA = LQ(JMATE-I)   pointer to the Ith material
  JDRAY = LQ(JMA-11)   pointer to δ-ray cross-sections
  JDRAY   pointer for electrons
  JDRAY+90   pointer for positrons
  JDRAY+180   pointer for μ^+/μ^-.

The routine is called during initialisation by GPHYSI.

2   Method

Let:

$$\frac{d\sigma(E,T)}{dT}$$

be the differential cross-section for the ejection of an electron with kinetic energy T by an incident $e^{\pm}$ of total energy E moving in a medium of density ρ.

The variable DCUTE in common /GCCUTS/ is the kinetic energy cut-off for the generated δ-rays. Below this threshold the soft electrons ejected are simulated as continuous energy loss by the incident $e^{\pm}$, and above it they are explicitly generated.

The mean value of the energy lost by the incident $e^\pm$ to the soft δ-rays is:

$$E_{soft}(E, \texttt{DCUTE}) = \int_0^{\texttt{DCUTE}} \frac{d\sigma(E,T)}{dT} T\, dT \tag{1}$$

whereas the total cross-section for the ejection of an electron of energy $T > \texttt{DCUTE}$ is:

$$\sigma(E, \texttt{DCUTE}) = \int_{\texttt{DCUTE}}^{T_{Max}} \frac{d\sigma(E,T)}{dT}\, dT \tag{2}$$

where T_{Max} is the maximum energy transferable to the free electron:

$$T_{Max} = \begin{cases} E - m & for \ \ e^+ \\ (E-m)/2 & for \ \ e^-, \end{cases} \tag{3}$$

where m is the electron mass. The method of calculation of the continuous energy loss and the total cross-section are explained below. [PHYS331] deals with the explicit simulation of the δ-rays.

2.1 Continuous energy loss

The integration of (1) leads to the Berger-Seltzer formulae [50, 51, 52, 12, 53, 54]:

$$\frac{dE}{dx} = \frac{2\pi r_0^2 mn}{\beta^2} \left[\ln \frac{2(\tau+2)}{(I/m)^2} + F^\pm(\tau, \Delta) - \delta \right], \tag{4}$$

where

γ	$\dfrac{E}{m}$
β^2	$1 - \dfrac{1}{\gamma^2}$
τ	$\gamma - 1$
τ_c	$\dfrac{\texttt{DCUTE}}{m}$
$\texttt{DCUTE}$	energy cut for $e^\pm$
τ_{max}	maximum possible energy transfer in e$^-$ mass: τ for e$^+$, $\tau/2$ for e$^-$
Δ	$\min(\tau_c, \tau_{max})$
n	electron density of the medium
I	average mean ionisation energy
δ	density effect correction.

The functions $F^\pm$ are given by

$$F^+(\tau, \Delta) = \ln(\tau\Delta) - \frac{\Delta^2}{\tau}\left[\tau + 2\Delta - \frac{3\Delta^2 y}{2} - \left(\Delta - \frac{\Delta^3}{3}\right) y^2 - \left(\frac{\Delta^2}{2} - \tau\frac{\Delta^3}{3} + \frac{\Delta^4}{4}\right) y^3 \right] \tag{5}$$

$$F^-(\tau, \Delta) = -1 - \beta^2 + \ln\left[(\tau - \Delta)\Delta\right] + \frac{\tau}{\tau - \Delta} + \frac{\left[\frac{\Delta^2}{2} + (2\tau + 1)\ln\left(1 - \frac{\Delta}{\tau}\right)\right]}{\gamma^2}, \tag{6}$$

where $y = 1/(\gamma+1)$.

The density effect correction is calculated as in [53]:

$$\delta = \begin{cases} 0 & \text{if } x < x_0 \\ 2\ln 10 + x + C + a(x_1 - x)^m & x_0 \leq x \leq x_1 \\ 2\ln 10 + x + C & x_1 < x, \end{cases} \tag{7}$$

where $x = \ln(\gamma^2 - 1)/(2\ln 10)$ The quantities n, I and the parameters of the density effect correction (x_0, x_1, C, a, m) are computed in the routine GPROBI, and we give the corresponding formulae here. The electron density of the medium, n, can be written as

$$n = \begin{cases} N_{Av}\rho\dfrac{Z}{A} & \text{for elements} \\[2ex] N_{Av}\rho\dfrac{\sum_i n_i Z_i}{\sum_i n_i A_i} & \text{for compounds/mixtures,} \end{cases} \tag{8}$$

where

N Avogadro's number;
Z_i atomic number;
A_i atomic weight;
ρ density of the material;
n_i proportion by number of the ith element in the material (for a mixture $n_i = W p_i/A_i$ where p_i the proportion by weight and W is the molecular weight).

The average mean ionisation energy can be calculated as [50] [51] [52] [12]:

$$I(GeV) = \begin{cases} 16 \cdot 10^{-9}\ Z^{0.9} & \text{for a chemical element} \\[2ex] \exp\left[\sum_i n_i Z_i \ln I(Z_i)/\sum_i n_i Z_i\right] & \text{for a compound or mixture} \end{cases} \tag{9}$$

The density effect correction parameters can be computed (for condensed medium [53]) as

$$\begin{aligned} C &= 1 + 2\ln\frac{I}{28.8 \cdot 10^{-9}\sqrt{\rho\sum n_i Z_i/\sum n_i A_i}} \\[2ex] m &= 3 \\[1ex] x_a &= \frac{C}{2\ln 10} \\[2ex] a &= 2\ln 10\frac{(x_a - x_0)^m}{(x_1 - x_0)} \end{aligned}$$

I	C	x_0	x_1
$< 10^{-7}$	< 3.681	0.2	2
$< 10^{-7}$	≥ 3.681	$-0.326C - 1$	2
$\geq 10^{-7}$	5.215	0.2	3
$\geq 10^{-7}$	≥ 5.215	$-0.326C - 1.5$	3

2.2 Total cross-sections

The integration of formula (2) gives the total cross-section [15], [17] for Möller scattering ($e^- e^-$):

$$\sigma(Z, E, \text{DCUTE}) = \frac{2\pi r_0^2 mZ}{\beta^2(E - m)}\left[\frac{(\gamma - 1)}{\gamma^2}\left(\frac{1}{x} - 1\right) + \frac{1}{x} - \frac{1}{1-x} - \frac{2\gamma - 1}{\gamma^2}\ln\frac{1-x}{x}\right] \tag{10}$$

and for Bhabha scattering ($e^+ e^-$):

$$\sigma(Z, E, \text{DCUTE}) = \frac{2\pi r_0^2 mZ}{(E - m)}\left[\frac{1}{\beta^2}\left(\frac{1}{x} - 1\right) + B_1 x + B_2(1 - x) - \frac{B_3}{2}(1 - x^2) + \frac{B_4}{3}(1 - x^3)\right] \tag{11}$$

where

$$\gamma = \frac{E}{m}$$

$$\beta^2 = 1 - \frac{1}{\gamma^2}$$

$$x = \frac{\text{DCUTE}}{E - m}$$

$$\gamma = \frac{1}{\gamma + 1}$$

$$B_1 = 2 - y^2$$

$$B_2 = (1 - 2y)(3 + y^2)$$

$$B_3 = (1 - 2y)^2 + (1 - 2y)^3$$

$$B_4 = (1 - 2y)^3$$

The formulae [10] and [11] give the total cross-section of the scattering above the threshold energies

$$T^{thr}_{Moller} = \text{2DCUTE} \qquad \text{and} \qquad T^{thr}_{Bhabha} = \text{DCUTE} \qquad (12)$$

The interaction length for the production of δ-rays is calculated during initialisation by routine GDRSGA.

Simulation of the delta-ray production

1   Subroutines

```
CALL GDRAY
```

`GDRAY` generates explicitly the delta-rays (see [PHYS330] for treatment of the ionization as continuous energy loss and for the calculation of the total cross-section).

```
input:      common /GCTRAK/
output:     common /GCKING/
```

The routine is called from the tracking routines `GTELEC`, `GTMUON`, `GTHION` and `GTHADR` when a charged particle reaches its interaction point.

2   Method

2.1   Differential cross-section

The differential cross-section of the δ-ray production can be written as in equations (1, 2) [54], [12], [55]. For the electron/electron (Möller) scattering we have:

$$\frac{d\sigma}{d\epsilon} = \frac{2\pi Z r_0^2 m}{\beta^2 (E - m)} \left[\frac{(\gamma - 1)^2}{\gamma^2} + \frac{1}{\epsilon} \left(\frac{1}{\epsilon} - \frac{2\gamma - 1}{\gamma^2} \right) + \frac{1}{1 - \epsilon} \left(\frac{1}{1 - \epsilon} - \frac{2\gamma - 1}{\gamma^2} \right) \right] \tag{1}$$

and for the positron-electron (Bhabha) scattering:

$$\frac{d\sigma}{d\epsilon} = \frac{2\pi Z r_0^2 m}{(E - m)} \left[\frac{1}{\beta^2 \epsilon^2} - \frac{B_1}{\epsilon} + B_2 - B_3 \epsilon + B_4 \epsilon^2 \right] \tag{2}$$

where

$$
\begin{array}{llll}
Z &=& \text{atomic number of the medium} & \qquad E &=& \text{energy of the incident particle} \\
M &=& \text{rest mass of the incident particle} & \qquad \gamma &=& \dfrac{E}{M} \\
\beta^2 &=& 1 - \dfrac{1}{\gamma^2} & \qquad y &=& \dfrac{1}{\gamma + 1} \\
B_1 &=& 2 - y^2 & \qquad B_2 &=& (1 - 2y)(3 + y^2) \\
B_3 &=& (1 - 2y)^2 + (1 - 2y)^3 & \qquad B_4 &=& (1 - 2y)^3 \\
\epsilon &=& \dfrac{T}{E - m} & &
\end{array}
$$

with T the kinematic energy of the scattered electron (of the lower energy in the case of $e^- e^+$ scattering).

The kinematical limits for the variable ϵ are:

$$\epsilon_0 = \frac{\texttt{TCUT}}{E - m} \leq \epsilon \leq \frac{1}{2} \quad \text{for } e^- e^- \qquad\qquad \epsilon_0 = \frac{\texttt{TCUT}}{E - m} \leq \epsilon \leq 1 \quad \text{for } e^+ e^-$$

For the other charged particles the differential cross-section can be written:

$$\frac{d\sigma}{dT} = 2\pi Z r_0^2 m \frac{1}{\beta^2} \frac{1}{T^2} \left[1 - \beta^2 \frac{T}{\text{TMAX}} \right] \qquad \text{for spin 0 particle}$$

$$\frac{d\sigma}{dT} = 2\pi Z r_0^2 m \frac{1}{\beta^2} \frac{1}{T^2} \left[1 - \beta^2 \frac{T}{\text{TMAX}} + \frac{T^2}{2E^2} \right] \qquad \text{for spin 1/2 particle}$$

where TMAX is the maximum energy transferable to the free electron:

$$\text{TMAX} = \frac{2m(\gamma^2 - 1)}{1 + 2\gamma(m/M) + (m/M)^2}$$

and TCUT is the energy threshold for the δ-ray emission: $\text{TCUT} \leq T \leq \text{TMAX}$

2.2 Sampling

Apart from the normalisation, the cross-section can be written as

$$\frac{d\sigma}{d\epsilon} = f(\epsilon)g(\epsilon),$$

where, for e^-e^- scattering,

$$f(\epsilon) = \frac{1}{\epsilon^2} \frac{\epsilon_0}{1 - 2\epsilon_0}$$

$$g(\epsilon) = \frac{4}{9\gamma^2 - 10\gamma + 5} \left[(\gamma - 1)^2 \epsilon^2 - (2\gamma^2 + 2\gamma - 1)\frac{\epsilon}{1 - \epsilon} + \frac{\gamma^2}{(1 - \epsilon)^2} \right]$$

and for e^+e^- scattering

$$f(\epsilon) = \frac{1}{\epsilon^2} \frac{\epsilon_0}{1 - \epsilon_0}$$

$$g(\epsilon) = \frac{B_0 - B_1\epsilon + B_2\epsilon^2 - B_3\epsilon^3 + B_4\epsilon^4}{B_0 - B_1\epsilon_0 + B_2\epsilon_0^2 - B_3\epsilon_0^3 + B_4\epsilon_0^4}$$

Here $B_0 = \gamma^2/(\gamma^2 - 1)$ and all the other quantities have been defined above. For the other charged particles:

$$f(T) = \left(\frac{1}{\text{TCUT}} - \frac{1}{\text{TMAX}} \right) \frac{1}{T}$$

$$g(T) = 1 - \beta^2 \frac{T}{\text{TMAX}} + \frac{T^2}{2E^2} \qquad \text{(last term for spin-}\frac{1}{2}\text{ particle only)}$$

GDRAY samples the variable ϵ by:

1. sample ϵ from $f(\epsilon)$

2. calculate the rejection function $g(\epsilon)$ and accept the sampled ϵ with a probability of $g(\epsilon)$.

After the successful sampling of ϵ, GDRAY generates the polar angles of the scattered electron with respect to the direction of the incident particle. The azimuthal angle ϕ is generated isotropically; the polar angle θ is calculated from the energy momentum conservation. This information is used to calculate the energy and momentum of both scattered particles and to transform them into the GEANT coordinate system.

Simulation of energy loss straggling

1   Subroutines

    CALL **GFLUCT**   (DEMEAN,DE*)

DEMEAN   (`REAL`) average energy loss according to the energy loss tables;
DE   (`REAL`) actual energy loss.

`GFLUCT` selects the method to sample the fluctuations around the mean energy loss `DEMEAN` and returns the energy loss `DE` in the current step.

If δ-rays are not produced (`DRAY=0`), it calls `GLANDG` when the current particle and material parameters are in the validity range of Landau theory, `GVAVIV` when in the range of Vavilov theory, or performs a Gaussian sampling. For fluctuations in small steps `GLANDZ` is called.

If δ-rays are produced (`DRAY=1`), it calls `GLANDZ` which, the cut for the δ-ray production being set, does sampling from restricted formula.

`GFLUCT` is called from the tracking routines `GTELEC`, `GTHADR` and `GTMUON` when the `LOSS` flag is set to 1, 2 or 3.

    CALL **GLANDG**   (YRAN*)

YRAN   (`REAL`) random variable distributed according to the Landau distribution;

`GLANDG` samples from the Landau distribution. It is called from `GFLUCT`.

    VALUE = **GVAVIV**   (RKAPPA,BETA2,RAN)

RKAPPA   (`REAL`) κ parameter of the Vavilov distribution (see below);
BETA2   (`REAL`) β^2 of the particle;
RAN   (`REAL`) random number uniformly distributed in]0,1[.

`GVAVIV` samples samples the variable $\lambda = \lambda_v/\kappa - \ln \kappa$, sometimes called the Landau λ, where λ_v is distributed according to the Vavilov distribution. For more details see below. It is called from `GFLUCT`.

    CALL **GLANDZ**   (Z,STEP,P,E,DEDX,DE*,POTI,POTIL)

Z   (`REAL`) atomic number of the medium;
STEP   (`REAL`) step size in cm;
P   (`REAL`) momentum of the particle in GeV c^{-1};
E   (`REAL`) total energy of the particle in GeV;
DEDX   (`REAL`) average energy loss in the step according to the energy loss tables;
DE   (`REAL`) actual energy loss in the step;
POTI   (`REAL`) average ionisation potential for the medium;
POTIL   (`REAL`) logarithm of the average ionisation potential.

`GLANDZ` gives the energy loss `DE` for the current particle with energy `E` and momentum `P` in a material of atomic number `Z` where the average energy loss is `DEDX` and the current step length `STEP`. It is called from `GFLUCT` for restricted Landau fluctuations when δ-rays are produced or to sample the fluctuations in thin layers (with or without δ-ray production).

2   Method

Due to the statistical nature of ionisation energy loss, large fluctuations can occur in the amount of energy deposited by a particle traversing an absorber element. As recently reviewed [56], continuous processes such as multiple scattering and energy loss play a relevant role in the longitudinal and lateral development of electromagnetic and hadronic showers, and in the case of sampling calorimeters the measured resolution can be significantly affected by such fluctuations in their active layers. The description of ionisation fluctuations is characterised by the significance parameter κ, which is proportional to the ratio of mean energy loss to the maximum allowed energy transfer in a single collision with an atomic electron

$$\kappa = \frac{\xi}{E_{max}}$$

E_{max} is the maximum transferable energy in a single collision with an atomic electron.

$$E_{max} = \frac{2m_e\beta^2\gamma^2}{1 + 2\gamma m_e/m_x + (m_e/m_x)^2},$$

where $\gamma = E/m_x$, E is energy and m_x the mass of the incident particle, $\beta^2 = 1 - 1/\gamma^2$ and m_e is the electron mass. ξ comes from the Rutherford scattering cross section and is defined as:

$$\xi = \frac{2\pi z^2 e^4 N_{Av} Z \rho \delta x}{m_e \beta^2 c^2 A} = 153.4 \frac{z^2}{\beta^2} \frac{Z}{A} \rho \delta x \quad \text{keV},$$

where

z	charge of the incident particle
N_{Av}	Avogadro's number
Z	atomic number of the material
A	atomic weight of the material
ρ	density
δx	thickness of the material

κ measures the contribution of the collisions with energy transfer close to E_{max}. For a given absorber, κ tends towards large values if δx is large and/or if β is small. Likewise, κ tends towards zero if δx is small and/or if β approaches 1.

The value of κ distinguishes two regimes which occur in the description of ionisation fluctuations :

1. A large number of collisions involving the loss of all or most of the incident particle energy during the traversal of an absorber.

   As the total energy transfer is composed of a multitude of small energy losses, we can apply the central limit theorem and describe the fluctuations by a Gaussian distribution. This case is applicable to non-relativistic particles and is described by the inequality $\kappa > 10$ (i.e. when the mean energy loss in the absorber is greater than the maximum energy transfer in a single collision).

2. Particles traversing thin counters and incident electrons under any conditions.

   The relevant inequalities and distributions are $0.01 < \kappa < 10$, Vavilov distribution, and $\kappa < 0.01$, Landau distribution.

An additional regime is defined by the contribution of the collisions with low energy transfer which can be estimated with the relation ξ/I_0, where I_0 is the mean ionisation potential of the atom. Landau theory assumes that the number of these collisions is high, and consequently, it has a restriction $\xi/I_0 \gg 1$. In GEANT, the limit of Landau theory has been set at $\xi/I_0 = 50$. Below this limit special models taking into account the atomic structure of the material are used. This is important in thin layers and gaseous materials. Figure 37 shows the behaviour of ξ/I_0 as a function of the layer thickness for an electron of 100 keV and 1 GeV of kinetic energy in Argon, Silicon and Uranium.

In the following sections, the different theories and models for the energy loss fluctuation are described. First, the Landau theory and its limitations are discussed, and then, the Vavilov and Gaussian straggling functions and the methods in the thin layers and gaseous materials are presented.
Figure 37: The variable ξ/I_0 can be used to measure the validity range of the Landau theory. It depends on the type and energy of the particle, Z, A and the ionisation potential of the material and the layer thickness.

2.1 Landau theory

For a particle of mass m_x traversing a thickness of material δx, the Landau probability distribution may be written in terms of the universal Landau [57], [58] function $\phi(\lambda)$ as:

$$f(\epsilon, \delta x) = \frac{1}{\xi}\phi(\lambda)$$

where

$$\phi(\lambda) = \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}\exp\left(u\ln u + \lambda u\right)du \qquad c \geq 0$$

$$\lambda = \frac{\epsilon - \bar{\epsilon}}{\xi} - \gamma' - \beta^2 - \ln\frac{\xi}{E_{max}}$$

$$\gamma' = 0.422784\ldots = 1 - \gamma$$

$$\gamma = 0.577215\ldots\text{(Euler's constant)}$$

$$\bar{\epsilon} = \text{average energy loss}$$

$$\epsilon = \text{actual energy loss}$$

Restrictions

The Landau formalism makes two restrictive assumptions :

1. The typical energy loss is small compared to the maximum energy loss in a single collision. This restriction is removed in the Vavilov theory (see section 2.2).

2. The typical energy loss in the absorber should be large compared to the binding energy of the most tightly bound electron. For gaseous detectors, typical energy losses are a few keV which is comparable to the binding energies of the inner electrons. In such cases a more sophisticated approach which accounts for atomic energy levels (see for instance Talman [59]) is necessary to accurately simulate data distributions. In GEANT, a parameterised model by L. Urbán is used (see section 2.4).

In addition, the average value of the Landau distribution is infinite. Summing the Landau fluctuation obtained to the average energy from the dE/dx tables, we obtain a value which is larger than the one coming from the table. The probability to sample a large value is small, so it takes a large number of steps (extractions) for the average fluctuation to be significantly larger than zero. This introduces a dependence of the energy loss on the step size which can affect calculations.

A solution to this has been to introduce a limit on the value of the variable sampled by the Landau distribution [60], in order to keep the average fluctuation to 0. The value obtained from the GLANDO routine is:

$$\delta dE/dx = \epsilon - \bar{\epsilon} = \xi(\lambda - \gamma' + \beta^2 + \ln \frac{\xi}{E_{max}})$$

In order for this to have average 0, we must impose that:

$$\bar{\lambda} = -\gamma' - \beta^2 - \ln \frac{\xi}{E_{max}}$$

This is realised introducing a $\lambda_{max}(\bar{\lambda})$ such that if only values of $\lambda \leq \lambda_{max}$ are accepted, the average value of the distribution is $\bar{\lambda}$.

A parametric fit to the universal Landau distribution has been performed, with following result:

$$\lambda_{max} = 0.60715 + 1.1934\bar{\lambda} + (0.67794 + 0.052382\bar{\lambda}) \exp(0.94753 + 0.74442\bar{\lambda})$$

only values smaller than λ_{max} are accepted, otherwise the distribution is resampled.

2.2 Vavilov theory

Vavilov [61] derived a more accurate straggling distribution by introducing the kinematic limit on the maximum transferable energy in a single collision, rather than using $E_{max} = \infty$. Using the notations of [62] we can write:

$$f(\epsilon, \delta s) = \frac{1}{\xi}\phi_v(\lambda_v, \kappa, \beta^2)$$

where

$$\phi_v(\lambda_v, \kappa, \beta^2) = \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} \phi(s)e^{\lambda s}ds \qquad c \geq 0$$

$$\phi(s) = \exp[\kappa(1+\beta^2\gamma)] \exp[\psi(s)],$$

$$\psi(s) = s\ln\kappa + (s+\beta^2\kappa)[\ln(s/\kappa) + E_1(s/\kappa)] - \kappa e^{-s/\kappa},$$

and

$$E_1(z) = \int_z^\infty t^{-1} e^{-t} dt \qquad \text{(the exponential integral)}$$

$$\lambda_v = \kappa \left[\frac{\epsilon - \bar{\epsilon}}{\xi} - \gamma' - \beta^2 \right]$$

The Vavilov parameters are simply related to the Landau parameter by $\lambda_L = \lambda_v/\kappa - \ln \kappa$. It can be shown that as $\kappa \to 0$, the distribution of the variable λ_L approaches that of Landau. For $\kappa \leq 0.01$ the two distributions are already practically identical. Contrary to what many textbooks report, the Vavilov distribution *does not* approximate the Landau distribution for small κ, but rather the distribution of λ_L defined above tends to the distribution of the true λ from the Landau density function. Thus the routine GVAVIV samples the variable λ_L rather than λ_v. For $\kappa \geq 10$ the Vavilov distribution tends to a Gaussian distribution (see next section).

2.3 Gaussian Theory

Various conflicting forms have been proposed for Gaussian straggling functions, but most of these appear to have little theoretical or experimental basis. However, as noted by Schorr [62] it has been demonstrated by Seltzer and Berger [63] that for $\kappa \geq 10$ the Vavilov distribution can be replaced by a Gaussian of the form :

$$f(\epsilon, \delta s) \approx \frac{1}{\xi \sqrt{\frac{2\pi}{\kappa}(1 - \beta^2/2)}} \exp \left[\frac{(\epsilon - \bar{\epsilon})^2}{2} \frac{\kappa}{\xi^2(1 - \beta^2/2)} \right]$$

thus implying

$$\text{mean} = \bar{\epsilon}$$

$$\sigma^2 = \frac{\xi^2}{\kappa}(1 - \beta^2/2) = \xi E_{max}(1 - \beta^2/2)$$

2.4 Urbán model

The method for computing restricted energy losses with δ-ray production above given threshold energy in GEANT is a Monte Carlo method that can be used for thin layers. It is fast and it can be used for any thickness of a medium. Approaching the limit of the validity of Landau's theory, the loss distribution approaches smoothly the Landau form as shown in figure 38.

It is assumed that the atoms have only two energy levels with binding energy E_1 and E_2. The particle–atom interaction will then be an excitation with energy loss E_1 or E_2, or an ionisation with an energy loss distributed according to a function $g(E) \sim 1/E^2$:

$$g(E) = \frac{(E_{max} + I)I}{E_{max}} \frac{1}{E^2} \tag{1}$$

The macroscopic cross-section for excitations $(i = 1, 2)$ is

$$\Sigma_i = C \frac{f_i}{E_i} \frac{\ln(2m\beta^2\gamma^2/E_i) - \beta^2}{\ln(2m\beta^2\gamma^2/I) - \beta^2}(1 - r) \tag{2}$$

and the macroscopic cross-section for ionisation is

$$\Sigma_3 = C \frac{E_{max}}{I(E_{max} + I)\ln(\frac{E_{max}+I}{I})} r \tag{3}$$

E_{max} is the GEANT cut for δ-production, or the maximum energy transfer minus mean ionisation energy, if it is smaller than this cut-off value. The following notation is used:

r, C parameters of the model

E_i atomic energy levels

I mean ionisation energy

f_i oscillator strengths
Figure 38: Energy loss distribution for a 3 GeV electron in Argon as given by standard `GEANT`. The width of the layers is given in centimeters.

The model has the parameters f_i, E_i, C and r $(0 \leq r \leq 1)$. The oscillator strengths f_i and the atomic level energies E_i should satisfy the constraints

$$f_1 + f_2 = 1 \tag{4}$$
$$f_1 \ln E_1 + f_2 \ln E_2 = \ln I \tag{5}$$

The parameter C can be defined with the help of the mean energy loss dE/dx in the following way: The numbers of collisions (n_i, i = 1,2 for the excitation and 3 for the ionisation) follow the Poissonian distribution with a mean number $\langle n_i \rangle$. In a step Δx the mean number of collisions is

$$\langle n_i \rangle = \Sigma_i \Delta x \tag{6}$$

The mean energy loss dE/dx in a step is the sum of the excitation and ionisation contributions

$$\frac{dE}{dx} \Delta x = \left[\Sigma_1 E_1 + \Sigma_2 E_2 + \Sigma_3 \int_I^{E_{max}+I} E \, g(E) \, dE \right] \Delta x \tag{7}$$

From this, using the equations (2), (3), (4) and (5), one can define the parameter C

$$C = \frac{dE}{dx} \tag{8}$$

The following values have been chosen in GEANT for the other parameters:

$$f_2 = \begin{cases} 0 & \text{if } Z \le 2 \\ 2/Z & \text{if } Z > 2 \end{cases} \quad \Rightarrow \quad f_1 = 1 - f_2$$

$$E_2 = 10\,Z^2 \text{ eV} \qquad\qquad \Rightarrow \quad E_1 = \left(\frac{I}{E_2^{f_2}}\right)^{\frac{1}{f_1}}$$

$$r = 0.4$$

With these values the atomic level E_2 corresponds approximately the K-shell energy of the atoms and $Z f_2$ the number of K-shell electrons. r is the only variable which can be tuned freely. It determines the relative contribution of ionisation and excitation to the energy loss.

The energy loss is computed with the assumption that the step length (or the relative energy loss) is small, and — in consequence — the cross-section can be considered constant along the path length. The energy loss due to the excitation is

$$\Delta E_e = n_1 E_1 + n_2 E_2 \tag{9}$$

where n_1 and n_2 are sampled from Poissonian distribution as discussed above. The loss due to the ionisation can be generated from the distribution $g(E)$ by the inverse transformation method:

$$u = F(E) \quad = \quad \int_I^E g(x)\,dx$$

$$E = F^{-1}(u) \quad = \quad \frac{I}{1 - u\frac{E_{max}}{E_{max}+I}} \tag{10}$$

$$\tag{11}$$

where u is a uniform random number between $F(I) = 0$ and $F(E_{max} + I) = 1$. The contribution from the ionisations will be

$$\Delta E_i = \sum_{j=1}^{n_3} \frac{I}{1 - u_j \frac{E_{max}}{E_{max}+I}} \tag{12}$$

where n_3 is the number of ionisation (sampled from Poissonian distribution). The energy loss in a step will then be $\Delta E = \Delta E_e + \Delta E_i$.

Fast simulation for $n_3 \ge 16$

If the number of ionisation n_3 is bigger than 16, a faster sampling method can be used. The possible energy loss interval is divided in two parts: one in which the number of collisions is large and the sampling can be done from a Gaussian distribution and the other in which the energy loss is sampled for each collision. Let us call the former interval $[I, \alpha I]$ the interval A, and the latter $[\alpha I, E_{max}]$ the interval B. α lies between 1 and E_{max}/I. A collision with a loss in the interval A happens with the probability

$$P(\alpha) = \int_I^{\alpha I} g(E)\,dE = \frac{(E_{max} + I)(\alpha - 1)}{E_{max}\,\alpha} \tag{13}$$

The mean energy loss and the standard deviation for this type of collision are

$$\langle \Delta E(\alpha) \rangle = \frac{1}{P(\alpha)} \int_I^{\alpha I} E\,g(E)\,dE = \frac{I\alpha \ln \alpha}{\alpha - 1} \tag{14}$$

and

$$\sigma^2(\alpha) = \frac{1}{P(\alpha)} \int_I^{\alpha I} E^2\,g(E)\,dE = I^2\alpha\left(1 - \frac{\alpha \ln^2 \alpha}{(\alpha - 1)^2}\right) \tag{15}$$

PHYS332 – 7

If the collision number is high , we assume that the number of the type A collisions can be calculated from a Gaussian distribution with the following mean value and standard deviation:

$$\langle n_A \rangle = n_3 P(\alpha) \tag{16}$$

$$\sigma_A^2 = n_3 P(\alpha)(1 - P(\alpha)) \tag{17}$$

It is further assumed that the energy loss in these collisions has a Gaussian distribution with

$$\langle \Delta E_A \rangle = n_A \langle \Delta E(\alpha) \rangle \tag{18}$$

$$\sigma_{E,A}^2 = n_A \sigma^2(\alpha) \tag{19}$$

The energy loss of these collision can then be sampled from the Gaussian distribution.

The collisions where the energy loss is in the interval B are sampled directly from

$$\Delta E_B = \sum_{i=1}^{n_3 - n_A} \frac{\alpha I}{1 - u_i \frac{E_{max} + I - \alpha I}{E_{max} + I}} \tag{20}$$

The total energy loss is the sum of these two types of collisions:

$$\Delta E = \Delta E_A + \Delta E_B \tag{21}$$

The approximation of equations ((16), (17), (18) and (19) can be used under the following conditions:

$$\langle n_A \rangle - c \, \sigma_A \geq 0 \tag{22}$$

$$\langle n_A \rangle + c \, \sigma_A \leq n_3 \tag{23}$$

$$\langle \Delta E_A \rangle - c \, \sigma_{E,A} \geq 0 \tag{24}$$

where $c \geq 4$. From the equations (13), (16) and (18) and from the conditions (22) and (23) the following limits can be derived:

$$\alpha_{min} = \frac{(n_3 + c^2)(E_{max} + I)}{n_3(E_{max} + I) + c^2 I} \leq \alpha \leq \alpha_{max} = \frac{(n_3 + c^2)(E_{max} + I)}{c^2(E_{max} + I) + n_3 I} \tag{25}$$

This conditions gives a lower limit to number of the ionisations n_3 for which the fast sampling can be done:

$$n_3 \geq c^2 \tag{26}$$

As in the conditions (22), (23) and (24) the value of c is as minimum 4, one gets $n_3 \geq 16$. In order to speed the simulation, the maximum value is used for α.

The number of collisions with energy loss in the interval B (the number of interactions which has to be simulated directly) increases slowly with the total number of collisions n_3. The maximum number of these collisions can be estimated as

$$n_{B,max} = n_3 - n_{A,min} \approx n_3(\langle n_A \rangle - \sigma_A) \tag{27}$$

From the previous expressions for $\langle n_A \rangle$ and σ_A one can derive the condition

$$n_B \leq n_{B,max} = \frac{2 n_3 c^2}{n_3 + c^2} \tag{28}$$

The following values are obtained with $c = 4$:

n_3	$n_{B,max}$	n_3	$n_{B,max}$
16	16	200	29.63
20	17.78	500	31.01
50	24.24	1000	31.50
100	27.59	∞	32.00

Special sampling for lower part of the spectrum

If the step length is very small ($\leq$ 5 mm in gases, $\leq$ 2-3 μm in solids) the model gives 0 energy loss for some events. To avoid this, the probability of 0 energy loss is computed

$$P(\Delta E = 0) = e^{-(\langle n_1 \rangle + \langle n_2 \rangle + \langle n_3 \rangle)} \tag{29}$$

If the probability is bigger than 0.01 a special sampling is done, taking into account the fact that in these cases the projectile interacts only with the outer electrons of the atom. An energy level $E_0 = 10$ eV is chosen to correspond to the outer electrons. The mean number of collisions can be calculated from

$$\langle n \rangle = \frac{1}{E_0} \frac{dE}{dx} \Delta x \tag{30}$$

The number of collisions n is sampled from Poissonian distribution. In the case of the thin layers, all the collisions are considered as ionisations and the energy loss is computed as

$$\Delta E = \sum_{i=1}^{n} \frac{E_0}{1 - \frac{E_{max}}{E_{max}+E_0} u_i} \tag{31}$$

3 Implementation

The method to be used for energy loss straggling is chosen in `GFLUCT`. If δ-rays are produced (`DRAY = 1`) above the cut value `DCUTE` and the detailed PAI simulation for straggling in thin layers (see PHYS334) is not chosen (`STRA = 0`, default), `GLANDZ` is called always as it samples from the restricted distribution (the energy loss of the δ-rays which are explicitly produced should not be taken into the energy loss distribution).

If δ-rays are not produced, the values of κ and ξ/I are computed, and Urbán, Landau, Vavilov or Gaussian model is chosen accordingly. If Urbán model is used, `GLANDZ` will be called with infinite (`BIG`) value for the δ-ray production.

When Landau model is chosen, it is possible to use a routine from the CERN Program Library to sample random numbers from the Landau distribution : `GENLAN` written by James and Hancock [64] and copied into `GEANT` source file as `GLANDG`. This routine has been modified in order to reproduce the tail for large values of X. The original routine did not give values of X larger than 200.

```
CALL GENLAN(X)
```

It should be noted that over the years considerable confusion has arisen over the precise form and features of the Landau distribution. As an example, a *simpler form* of $\phi(\lambda)$ had been proposed by Moyal [65] and used on occasions which has little in common with the function defined in section 2.1 [66].

For the Vavilov distribution we have used the function `GVAVIV` by Rotondi and Montagna [67].

Information about energy loss fluctuations

1   Subroutines

```
CALL GDRPRT  (IPART,IMATE,STEP,NPOINT)
```

IPART   (INTEGER) GEANT particle number;
IMATE   (INTEGER) GEANT material number;
STEP   (REAL) step in cm;
NPOINT   (INTEGER) number of logarithmically spaced energy points between EKMIN (default 10 keV)
             and EKMAX (default 10 TeV). See [BASE040] for more information on these value and how
             to change them with the ERAN input record;

This routine calculates and prints the relevant parameters relative to the simulation of energy loss fluctuations
due to ionisation and δ-ray production in STEP cm:

N d-rays   average number of δ-rays produced;
dE/I   average energy loss divided by the average ionisation potential;
xi/I   variable ξ/I of the Landau/Vavilov theory;
xi/Emax   variable ξ/E_{Max} of the Landau/Vavilov theory;
regime   valid model to simulate energy loss fluctuations. Possible values are:

       Gauss   Gauss distribution;
       Vavilov   Vavilov distribution;
       Landau   Landau distribution;
       Urbán   GLANDZ routine of Urban (see [PHYS332]);
       ASHO   atomic harmonic oscillator approximation (see [PHYS334]);
       PAI   Photo-Absorption Ionisation model (see [PHYS334]);

This routine has no action on the GEANT system. It is intended as a help to users understanding the model
which GEANT may be asked to use, for instance via the routine GSTPAR [CONS210].

2   Method

When a charged particle traverses a portion of matter, it interacts with the electrons and the nuclei of the
atoms. Most of these interactions are electromagnetic (quasi-) elastic collisions in which the incoming
particle loses energy in the laboratory reference frame. The amount of energy loss in a thickness of material
t is subject to two sources of fluctuations. The *number* of collisions can fluctuate, and at the same time the
energy lost in each collision varies statistically. Both distributions are characterised by a Poissonian-like
behaviour. We can distinguish between collisions where the energy transferred to the atomic electrons
is enough to extract them from the atoms (ionisation with production of δ-rays) and collisions where the
atomic structure is excited, without a complete ionisation (excitation). It has to be noted that the energy
transferred to the nuclei is usually negligible. Momentum conservation considerations show that the ratio
of the energy transferred to electrons to the energy transferred to nucleus in Coulomb interactions is of the
order of $m_e Z A^{-1} m_p^{-1}$.

Several theories have been proposed to describe this important mechanism in the transport of charged
particles. The main difference of these theories is in the greater or lesser detail with which the scattering

centres are described. The detail of these theories as they are implemented in `GEANT` can be found in [PHYS332], [PHYS334] for energy loss fluctuations and in [PHYS430], [PHYS431] for energy loss.

In general, the greater the thickness of the layer traversed in terms of the number of atoms encountered, the larger is the number of collisions. In this case a detailed description of the atomic structure may be irrelevant to account for the form of the fluctuation. Landau and Vavilov have proposed theories in this region and these are implemented in `GEANT`.

When the thickness of the material is such that the number of collisions becomes smaller, the detailed nature of the atomic structure becomes important in determining the fluctuations of the energy loss. In this case the coupling of the various atomic energy levels to the to the Coulomb field must be taken into account.

When simulating the energy loss by ionisation, the average path-length between collisions is a function of the cross section $\sigma(E)$. This cross section becomes very large when $E \to 0$, so that it is necessary to establish a threshold energy below which the process is described in a *condensed* way. Above this threshold, ionisations are described in a detailed way, with the production of δ-rays. Thus, when a charged particle is moving in a medium, there are in general two ways to simulate the energy loss by ionisation:

1. calculate the average value the energy loss via the full Bethe-Bloch equation. This takes into account δ-rays generation. The fluctuations are then explicitly introduced via an appropriate distribution. In `GEANT` this method is selected by the value `ILOSS = 2` which is controlled by the `LOSS` data record.

2. explicitly generate the δ-rays *above* a given threshold (`DCUTE` for electrons, `DCUTM` for others particle). In this case the average energy loss is computed from a restricted formula and both the value of the energy loss and the number of δ-rays produced are function of the threshold cut (hereafter `DRCUT`). In `GEANT` this method is selected by the value `ILOSS = 1` which is controlled by the `LOSS` data record.

2.1 Validity ranges for the different models

The limits of the validity for the various models are somewhat arbitrary within a certain range of material densities and particle energies. To help determine these limits, some characteristic parameters are used:

ξ typical energy loss of a particle in a given layer of material. Its value is:

$$\xi = 2\pi r_e^2 m_e c^2 N_{Av} \left(\frac{Z_{inc}}{\beta}\right)^2 \frac{Z\rho t}{A} = 0.1535 \left(\frac{Z_{inc}}{\beta}\right)^2 \frac{Z\rho t}{A} \, (MeV)$$

E_{Max} maximum transferable energy in a single collision:

$$E_{Max} = \frac{2m_e\beta^2\gamma^2}{1 + 2\gamma\frac{m_e}{M} + \left(\frac{m_e}{M}\right)^2}$$

where M is the mass of the incoming particle. Note that for incoming electrons this value has to be divided by 2 due to the impossibility distinguishing the two electrons in the final state.

I typical electron binding energy. This is a value which characterises the average energy levels of the atomic electrons. In `GEANT` it is parametrised as:

$$I = 16 Z^{0.9} \, (eV)$$

$\frac{dE}{dx} t$ average energy loss by the particle in a layer of thickness t according to the `GEANT` energy loss tables.

ξ/E_{Max} (hereafter κ) relative importance of high energy transfer collisions in the ionisation process

$\min\left(\frac{dE}{dx} t, \xi\right)/I$ (hereafter Δ) estimation of the number of collisions with energy close to the ionisation energy.

In `GEANT` two variables control the model used to describe the energy loss fluctuations:

`ILOSS` fluctuation model:

0	no energy loss;
1	δ-rays are produced above the threshold, *reduced* fluctuations from δ-rays below the threshold are added to the energy loss;
2	no δ-rays are produced, complete fluctuations are calculated;
3	same as 1;
4	no fluctuations;

ISTRA   energy loss model for *thin* layer (see below):

0	Urbán model;
1	PAI model;
2	ASHO model for $1 < \Delta \le 30$,(not yet available) PAI model otherwise;

The validity limits of the different models are estimated as follows:

1. **large number of low-energy collisions:** $\Delta \ge 50$

   if δ-rays generation is requested (`ILOSS = 1` or `3` and `IDRAY = 1`) the Urbán model is used. If δ-rays are not produced (`ILOSS = 2` and `IDRAY = 0`) we distinguish three regions:

   (a) **very few energy transfers close to the maximum:** $\kappa \le 10^{-2}$
       the Landau distribution is used;

   (b) **few energy transfers close to the maximum:** $10^{-2} < \kappa \le 10$
       the Vavilov distribution is used;

   (c) **many energy transfers close to the maximum:** $\kappa > 10$
       the Gauss distribution is used;

2. **small number of low-energy collisions:** $\Delta < 50$

   in this region the same model is used for $1 \le$ `ILOSS` ≤ 3 irrespective of the value of `IDRAY`. The model used depends on the value of `ISTRA`.

   (a) $30 < \Delta \le 50$
       Urbán model if `ISTRA` $= 0$, PAI model otherwise.

   (b) $1 < \Delta \le 30$
       Urbán model if `ISTRA` $= 0$, PAI model if `ISTRA` $= 1$ and ASHO model if `ISTRA` $= 2$.

   (c) $0.01 < \Delta \le 1$
       Urbán model if `ISTRA` $= 0$, PAI model otherwise.

   (d) $\Delta \le 0.01$
       Urbán model if `ISTRA` $= 0$, PAI model otherwise.

2.2   Recommendations

The full energy loss fluctuations or the restricted fluctuations complemented by the production of δ-rays give equivalent results if the number of δ-rays generated is sufficient, e.g. a few tens along the full trajectory of the particle in the medium.

For a relativistic particle, the number of delta-rays produced per cm can be estimated integrating the cross section provided in [55]:

$$\frac{dN}{dx} \approx \frac{D}{2} \frac{\rho Z}{A} \frac{Z_{inc}^2}{\text{DRCUT}} \tag{1}$$

where

D	0.307 MeV cm^2 g^{-1};
ρ	density of the medium;

Z, A atomic number and atomic weight of the medium;

Z_{inc} charge of the particle;

DRCUT   energy threshold for emitted delta-rays.

This formula holds for electrons/positrons as well as for other particles. The number of δ-rays must be sufficient to reproduce the statistical fluctuations in the energy loss, but not too large, as in this case a large amount of time could be spent in tracking them without a corresponding improvement of the energy loss distribution.

On the other hand, the distribution of the energy *lost* by a particle does not necessarily correspond to the distribution of the energy *deposited* by the same particle in the medium traversed. This is particularly true for light or *thin* materials where δ-rays can escape into the next material.

It is the responsibility of the user to estimate the number of δ-rays per cm that are needed, according to the considerations above. Then the correct value for DRCUT should be set with the help of GDRPRT. It is recommended to use the same value for DCUTE and DCUTM. As the GEANT tables for cross-sections are not generated below EKMIN, DRCUT cannot be smaller than EKMIN. The value of EKMIN can be changed via the ERAN data record, and its default value is 10 keV.

In a *light* material like gas, the number of emitted δ-rays for DRCUT $=$ 10 keV may not be sufficient to ensure a correct energy loss distribution. If the user is mainly interested in the energy lost by the particle, no discrete δ-ray should be produced setting ILOSS $=$ 2 (see [PHYS332]).

In case the user is more interested in a precise simulation of the energy deposited, then the explicit δ-ray generation should be tried.

As far as *thin* materials are concerned ($\Delta < 50$), the default in GEANT is to use the Urbán model. Comparison with experimental data have shown that this model gives very good results, and it is considerably faster than both the ASHO and the PAI models. Users should understand well their setup and their results before they try with different models, which, in principle, should give very similar results.

2.3   Default values in GEANT

In order to avoid double counting, there is an automatic protection in the code: *if ILOSS=2, IDRAY is set to 0 and the generation of δ-rays is disabled*.

The following table summarises the different cases:

	LOSS=2 (default)	LOSS=1
IDRAY	0	1
DCUTE	10^4 GeV	CUTELE
DCUTM	10^4 GeV	CUTELE

Where LOSS$=$ 1 means that the restricted fluctuation is activated and LOSS$=$ 2 means that the complete Landau/Vavilov/Gauss fluctuations are used in the region $\Delta \geq 50$.

Models for energy loss fluctuations in thin layers

1   Subroutines

```
   CALL GSTINI
```

`GSTINI` initializes the tables that are used for sampling of the energy loss, if the user has set the flag `STRA` = `1`. It calls the subroutine `GSTXIN` to integrate an expression for the number of collisions and `GSTTAB` for preparing the tables for different Lorentz factors. It is called from `GPHYSI` at initialization time.

```
   CALL GSTXIN
```

`GSTXIN` computes the values needed for the sampling tables. It uses the functions `GOSCIN` to integrate over the photoelectric cross-sections and the function `GKOKRI` to compute the real part of the complex dielectric constant. `GSTXIN` is called from `GSTINI`.

```
   VALUE = GOSCIN (EIN1EV,EIN2EV)
```

`GOSCIN` integrates the parameterization of the photoelectric cross-sections from energy `EIN1EV` to energy `EIN2EV`. It is called from `GSTXIN`.

```
   VALUE = GKOKRI (E,EMINEV,EMAXEV)
```

`GKOKRI` computes the real part of the complex dieletric constant which is needed in the preparation of energy loss sampling tables. `E` in the energy for which the values are being tabulated, `EMINEV` and `EMAXEV` are the integration limits. `GKOKRI` is called from `GSTXIN`.

```
   CALL GSTTAB (GAM,NT,EN,FN)
```

`GSTTAB` prepares the energy loss sampling tables for different Lorentz factors. The input `GAM` is the Lorentz factor, the output values are: `NT` the lenght of the table, `EN` the energy array and `FN` the cumulative probabilty array. It calls `GXGINT` to integrate over the probability function `GSTDN` to get the value of `FN`. `GSTTAB` is called from `GSTINI`.

```
   VALUE = GXGINT (EXT,A,B,EPS)
```

`GXGINT` performs the Gaussian integration from `A` to `B` over the function `EXT` with accuracy `EPS`. It is called from `GSTTAB` to integrate over the probability function `GSTDN`.

```
   VALUE = GSTDN (LGE)
```

`GSTDN` is the function which gives the probability for a collision with energy transfer `LGE`. It is integrated to get the cumulative probabilty function to be used in the sampling of the energy loss.

```
   CALL GSTREN (GAMMA,ECUT,STEP)
```

`GSTREN` computes the energy loss for a particle of Lorentz factor `GAMMA` in a step of length `STEP` if the user has set the flag `STRA` = `1`. `ECUT` is the cut for the δ-ray production. `GSTREN` is called from `GFLUCT`.

2   The method

In thin layers, the Landau model of energy loss fluctuations is not valid, because the number of collisions is too small. In this case, the atomic structure of the atom has to be taken into account. The photoabsorption ionization (PAI) model uses the photoelectric cross-sections to describe the energy loss distribution. The results (the width and the most probable value of the energy loss distribution function) given by this model are equal to those given by standard `GEANT` procedure described in [PHYS332]. In addition, however, it gives an estimate of the number of collision in each step (`NICOLL` in the common block `GCSTRA`). PAI model is slower than the standard `GEANT` method.

PAI model is activated, if the user set the flag `STRA = 1`. The default value is 0.

2.1   The photoabsorption ionization model

An expression for the distribution of energy loss can be derived considering the energy loss as the sum of the energy transfers in the electromagnetic interactions between the particle and the atom. As the interaction is small (i.e. the energy transfer is small compared to the energy of the passing particle), Born approximation can be used in the perturbation theory. In the derivation, the atomic transition current is considered as a sum of the transition currents of its electrons.

ε is the complex dielectric constant of a medium which describes the electromagnetic properties of the medium and thus the effect of the field of an atom on the energy loss of the particle.

The complex dielectric constant can be written $\varepsilon = \varepsilon_1 + i\varepsilon_2$ where ε_1 describes the polarization and ε_2 the absorptive properties of the medium. ε_2 can be expressed with the help of the oscillator strength function $f(k,\omega)$ which describes the coupling of the electrons to the field of the atom.

$$\varepsilon_2 = \frac{2\pi^2 N e^2}{m\omega} f(k,\omega) \tag{1}$$

m is the mass of the electron and N is the electron density. In a simplified model, the photoabsorption cross-section $\sigma_\gamma(\omega)$ can be used for description of $f(k,\omega)$:

$$f(k,\omega) = \frac{mc}{2\pi^2 e^2 Z} \sigma_\gamma(\omega) \tag{2}$$

Z being the atomic number of the medium. The real part of ε can be expressed as an integral of the imaginary part according to the Kronig's and Kramers' dispersion relation [68]:

$$
\begin{aligned}
\varepsilon_1 - 1 &= \frac{2}{\pi} P \int_0^\infty \frac{x\varepsilon_2(x)dx}{x^2 - \omega^2} \\
&= \frac{2Nc}{\pi Z} P \int_0^\infty \frac{\sigma_\gamma(x)dx}{x^2 - \omega^2}
\end{aligned} \tag{3}
$$

where P indicates the Cauchy principal value. Using these assumptions for the interaction between the projectile and the atom, the following form is obtained for the collision cross-section [69]:

$$
\begin{aligned}
\frac{d\sigma}{dE} &= -\frac{e^2}{\pi\hbar^2 c^2 n_a} \text{Im}\left[\left(\frac{1}{\beta^2\varepsilon} - 1\right)\ln\frac{2mv^2}{E(1-\beta^2\varepsilon)}\right] \\
&+ \frac{2\pi Z e^4}{mv^2 E^2}\int_0^\infty \frac{f(E')}{\varepsilon(E')^2}dE'
\end{aligned} \tag{4}
$$

where n_a is the number of atoms per cm³, v velocity of the particle, and $\beta = v/c$. The number of collisions per distance x and the energy E is then

$$\frac{N^2}{dx\,dE} = n_a \frac{d\sigma}{dE} \tag{5}$$

For the simulation purposes, the number of primary collisions in a unit length with energy loss greater than a certain E is computed and tabulated for several values of the Lorentz factor. This is done by integrating

$$\left(\frac{dN}{dx}\right)_{>E} = \int_E^{E_{max}} n_a \frac{d\sigma}{dE} dE \tag{6}$$
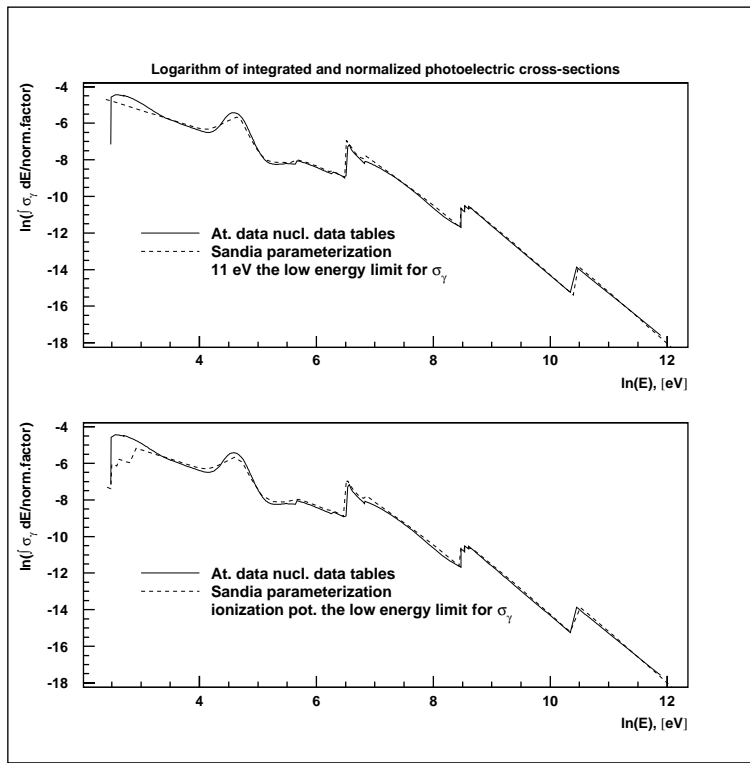

Figure 39: Above, the integrated and normalized cross-section of the gas mixture 70% Xe - 10% CO_2 - 20% CF_4 for two different data sets. The low energy limit of the cross-sections from the Sandia data in chosen to be 11 eV. In the figure below, the low energy limit is the ionization limit for each component of the mixture

2.2   Implementation

A photoabsorption ionization Monte Carlo code provided to us by users has been implemented in GEANT. Tables are prepared at initialization time and sampling from these tables is done each step at running time. An important thing to note is the dependence of the $(dN/dx)_{>E}$ on the photoelectric cross-sections which, when taken from different sources, may differ considerably, especially at low energies.

To fill the tables, the integration of equation 4 has to be done. Before the integration over the energy, the integral over the oscillator strength function $f(k, \omega) \sim \sigma_\gamma(\omega)$ (last term in equation 4) and the dielectric constant (equations 3 and 1) ε have to be computed. These integaration can be done analytically when the parameterized cross-sections are used.

The oscillator strength function should fulfill the Bethe sum rule [51]:

$$\int_0^\infty f(k, \omega)d\omega = 1 \tag{7}$$

To respect this condition, in the PAI model, one has to add some contribution from the excitation processes to low-energy region of the photoelectric cross-sections [68]. In GEANT, the photoelectric cross-section parameterization of the Sandia [19] report is used. In order not to change the tabulated parameterization, the sum rule is taken into account by lowering the energy limit for the integration below the ionization limit. This will not satisy the equation 7 in all cases. In the program, however, the Bethe sum rule is forced by dividing the integrated cross-section from E to ∞ by the value given by the integration over the whole range. In figure 39, the integrated cross-section (oscillator strength function) $\int_E^{E_{max}} \sigma_\gamma / \int_{E_0}^{E_{max}} \sigma_\gamma$ is given for two different sets of photoelectric cross-section data for a gas mixture 70% Xe - 10% CO_2 - 20% CF_4. In the figure below, the continuous line is the result of the integration tabulated from [70] [71] [72] and the dashed line is from the integration of GEANT cross-sections considering the lower limit of the cross-section the ionization energy (12.3 eV for Xe, 11.26 eV for C, 13.6 for O, and 17.42 for F). In the figure above, the
Figure 40: Above, the integrated and normalized cross-section of the gas mixture 70% Xe - 10% CO_2 - 20% CF_4 for two different data sets. The low energy limit of the cross-sections from the Sandia data in chosen to be 11 eV. In the figure below, the low energy limit is the ionization limit for each component of the mixture

continuous line is as before, but for the dashed line, the lower limit of the cross-sections is considered to be 11 eV for all elements of the mixture to compensate for the sum rule.

The imaginary part of the complex dielectric constant can then be computed from the integrated cross-section. To compute the real part of ε, one needs to take the Cauchy principal value which is basically a limiting process cancelling the two infinite contribution around the pole $(x_0 - \delta, x_0 + \delta)$. The derivation of the real part with the Sandia parametrization is shown in detail in the appendix.

Knowing the values of complex dielectric constant and the integrated cross-section, the integration of equation 6 can be done. This is done for several values of Lorentz factor during the initialization time in subroutine GSTINI. The value of energy loss is sampled from these tables in subroutine GSTREN.

One should remember the dependence of this method on the photoelectric cross section data. Figure 40 shows the results for the two different data sets. The difference in the low-energy part is very significative as the sampling is done from these tables and, according the inverse transverse method, the number of collisions is sampled between the maximum and minimum of the curves in figure 40.

Birks' saturation law

1   Subroutines

CALL **GBIRK**   (EDEP)

EDEP   (REAL) and on output the energy equivalent to the calorimeter response in the current step.

Organic scintillators are usually calibrated with particles whose energy is near the minimum ionisation ($\gamma\beta \approx 4$). However, the energy response of such scintillators for large local energy deposit is attenuated. GBIRK returns the energy *detected* by the scintillator in the current step.

2   Method

The phenomenological description of the response attenuation of organic scintillators [73] is known as Birks' law:

$$R = \frac{\Delta E}{1 + C_1 \delta + C_2 \delta^2} \qquad\qquad \delta = \frac{1}{\rho}\frac{dE}{dx} \quad \text{MeV g}^{-1}\text{ cm}^2 \tag{1}$$

The values quoted in [74] for the parameters C_1, C_2 are:

$$C_1 = 0.013 \text{ g MeV}^{-1}\text{ cm}^{-2} \qquad\qquad \text{and} \qquad\qquad C_2 = 9.6 \times 10^{-6} \text{ g}^2 \text{ MeV}^{-2}\text{ cm}^{-4}$$

These values have been measured for various scintillators. If the charge of the particle is greater than one, a better description can be obtained by correcting C_1:

$$C_1' = \frac{7.2}{12.6}C_1 \approx 0.5714 C_1 \tag{2}$$

The values of the parameters of Birks' formula (if defined) are in the ZEBRA bank next to the material bank:

JTM = LQ(JMATE-NTMED)   pointer to the current tracking medium bank;
JTMN = LQ(JTM)   pointer to the *next* bank to the current material one, where the specific tracking medium parameters are stored;
MODEL = Q(JTMN+27)   flag controlling the correction (2) for multiply charged particles:

                                $\neq 1$ correction is not applied;
                                $=1$ correction is applied;

C1 = Q(JTMN+28)   first parameter of the Birks' formula;
C2 = Q(JTMN+29)   second parameter of the Birks' formula.

These parameters are set via the GSTPAR routine, with names BIRK1, BIRK2 and BIRK3, respectively. For instance, to define the standard Birks' parameters for tracking medium ITM with correction for multiply charged particles, one would have to insert the following piece of code, after the definition of tracking media but before the call to GPHYSI

```
CALL GSTPAR(ITM,'BIRK1',1.)
CALL GSTPAR(ITM,'BIRK2',0.013)
CALL GSTPAR(ITM,'BIRK3',9.6E-6)
```

Total cross-section and energy loss for bremsstrahlung by e^-/e^+

1   Subroutines

CALL **GBRELA**

GBRELA fills the tables for the energy loss of electrons, positrons and muons due to bremsstrahlung at initialisation time for different materials. The energy binning is set within the array ELOW (common /CGMULO/) in the routine GPHYSI. In the tables, the dE/dx due to bremsstrahlung is summed with that due to the ionisation. For energy loss of electrons and positrons, GBRELA calls the function GBRELE. Following pointers are used:

JMA = LQ(JMATE-I)   pointer to the Ith material;
JEL1 = LQ(JMA-1)   pointer to dE/dx for e^-;
JEL1+NEK1   pointer to dE/dx for e^+.

GBRELA is called at initialisation time by GPHYSI.

VALUE = **GBRELE** (ZZ,T,BCUT)

GBRELE calculates the energy loss due to bremsstrahlung of an electron with kinetic energy T in material with atomic number ZZ. It is called by GBRELA and for energies below the cut BCUT it adds the contribution of bremsstrahlung to. Above this cut, the bremsstrahlung process is simulated explicitly (see [PHYS341]) and tabulation of these continuous losses is not needed. GBRELE is called by GBRELA.

VALUE = **GBFLOS** (T,C)

GBFLOS calculates a weight factor for the positron continuous bremsstrahlung energy loss. T is the kinetic energy in GeV of the positron and C is the energy cut for bremsstrahlung (BCUTE). The value is the ratio of the energy loss due to bremsstrahlung of the positron to that of the electron so that: *<positron loss>* = GBFLOS × *<electron loss>*. GBFLOS is called by GBRELA.

CALL **GBRSGA**

GBRSGA calculates the total cross-section for bremsstrahlung in all materials. It tabulates the mean free path, $\lambda = \frac{1}{\Sigma}$ (in cm) as a function of medium and energy. The energy binning is set within the array ELOW (common /CGMULO/) in the routine GPHYSI. The following pointers are used:

JMA = LQ(JMATE-I)   pointer to the Ith material
JBREM = LQ(JMA-9)   pointer to bremsstrahlung cross-sections
JBREM   pointer for e^-
JBREM+NEK1   pointer for e^+
JBREM+2*NEK1   pointer for μ^+/μ^-

GBRSGA is called at initialisation time by GPHYSI.

VALUE = **GBRSGE** (ZZ,T,BCUT)

GBRSGE calculates the total cross-section of bremsstrahlung of an electron with kinetic energy T in material with atomic number ZZ. It is called by GBRSGA. For kinetic energies which are below the cut BCUT or for which bremsstrahlung process is not simulated explicitly (see [PHYS341]) it returns 0.

```
VALUE  =  GBFSIG   (T,C)
```

GBFSIG calculates a weight factor for the positron discrete (hard) bremsstrahlung cross section. `T` is the kinetic energy in GeV of the positron and C is the energy cut for bremsstrahlung (`BCUTE`). The value returned is the ratio of the positron bremsstrahlung cross-section to that of the electron so that: *<positron cross-section>* = `GBFSIG` $\times$ *<electron cross-section>*. `GBFSIG` is called by `GBRSGA`.

2 Method

Let's call $d\sigma(Z,T,k)/dk$ the differential cross-section for production of a photon of energy k by an electron of kinetic energy T in the field of an atom of charge Z, and k_c the energy cut-off below which the soft photons are treated as continuous energy loss (`BCUTE` in the program). Then the mean value of the energy lost by the electron due to soft photons is

$$E_{Loss}^{brem}(Z,T,k_c) = \int_0^{k_c} k \frac{d\sigma(Z,T,k)}{dk} dk \qquad (1)$$

whereas the total cross-section for the emission of a photon of energy larger than k_c is

$$\sigma_{brem}(Z,T,k_c) = \int_{k_c}^T \frac{d\sigma(Z,T,k)}{dk} dk \qquad (2)$$

Many theories of the bremsstrahlung process exist, each with its own limitations and regions of applicability. Perhaps the best synthesis of these theories can be found in the paper of S.M. Seltzer and M.J. Berger [75]. The authors give a tabulation of the bremsstrahlung cross-section $d\sigma/dk$ differential in the photon energy k, for electrons with kinetic energies T from 1 keV to 10 GeV. For electron energies above 10 GeV the screened Bethe-Heitler differential cross-section can be used [12, 35] together with the Midgal corrections [54, 76]. The first of the two Migdal corrections is important for very high electron energies only ($T \geq 1$ TeV) and has the effect of reducing the cross-section. The second Migdal correction is effective even at "ordinary" energies (100 MeV – 1 GeV) and it decreases the differential cross-section at photon energies below a certain fraction of the incident electron energy ($d\sigma/dk$ decreases significantly if $k/T \leq 10^{-4}$.)

2.1   Parameterisation of energy loss and total cross-section

Using the tabulated cross-section values of Seltzer and Berger together with the Migdal corrected Bethe-Heitler formula we have computed $\sigma(Z,T,k_c)$ and we have used these computed values as "data points" in the fitting procedure. Calculating the "low energy" ($T \leq 10$ GeV) data we have applied the second Midgal correction to the results of Seltzer and Berger. We have chosen the parameterisations:

$$\sigma(Z,T,k_c) = \frac{Z(Z+\xi_\sigma)(T+m)^2}{T(T+2m)}[\ln(T/k_c)]^\alpha F_\sigma(Z,X,Y) \quad \text{(barn)} \qquad (3)$$

and

$$E_{Loss}^{brem}(Z,T,k_c) = \frac{Z(Z+\xi_l)(T+m)^2}{(T+2m)} \left[\frac{k_c C_M}{T}\right]^\beta F_l(Z,X,Y) \quad \text{(GeV barn)} \qquad (4)$$

where m is the mass of the electron,

$$X = \ln(E/m), \quad Y = \ln(v_\sigma E/k_c) \qquad \text{for the total cross-section } \sigma$$
$$X = \ln(T/m), \quad Y = \ln(k_c/v_l E) \qquad \text{for the energy loss } E_{Loss}^{brem}$$

with $E = T + m$. The constants ξ_σ, ξ_l, α, β, v_σ, v_l are parameters to be fitted.

$$C_M = \frac{1}{1 + \dfrac{nr_0 \lambda^2 (T+m)^2}{\pi k_c^2}}$$

is the Midgal correction factor, with

r_o classical electron radius;

λ reduced electron Compton wavelength;

n electron density in the medium.

The factors $(T+m)^2/T(T+2m)$ and $(T+m)^2/(T+2m)$ come from the scaled cross-section computed by Seltzer and Berger:

$$f(k/T) = \frac{\beta^2}{Z^2}k\frac{d\sigma}{dk} = \frac{T(T+2m)}{(T+m)^2 Z^2}k\frac{d\sigma}{dk}$$

The functions $F_i(Z, X, Y)$ $(i = \sigma, l)$ have the form

$$F_i(Z, X, Y) = F_{i0}(X, Y) + Z F_{i1}(X, Y) \tag{5}$$

where $F_{ij}(X, Y)$ are polynomials of the variables X, Y

$$\begin{aligned}
F_{i0}(X,Y) &= (C_1 + C_2 X + \ldots + C_6 X^5) + (C_7 + C_8 X + \ldots + C_{12} X^5)Y \\
&\quad + (C_{13} + C_{14}X + \ldots + C_{18}X^5)Y^2 + \ldots + (C_{31} + C_{32}X + \ldots + C_{36}X^5)Y^5 \quad (6)\\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad Y \le 0 \\
&= (C_1 + C_2 X + \ldots + C_6 X^5) + (C_7 + C_8 X + \ldots + C_{12}X^5) \\
&\quad + (C_{37} + C_{38}X + \ldots + C_{42}X^5)Y^2 + \ldots + (C_{55} + C_{56}X + \ldots + C_{60}X^5)Y^5 \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad Y > 0 \\
F_{i1}(X,Y) &= (C_{61} + C_{62}X + \ldots + C_{65}X^4) + (C_{66} + C_{67}X + \ldots + C_{70}X^4)Y \\
&\quad + (C_{71} + C_{72}X + \ldots + C_{75}X^4)Y^2 + \ldots + (C_{81} + C_{82}X + \ldots + C_{85}X^4)Y^4 \quad (7)\\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad Y \le 0 \\
&= (C_{61} + C_{62}X + \ldots + C_{65}X^4) + (C_{66} + C_{67}X + \ldots + C_{70}X^4)Y \\
&\quad + (C_{86} + C_{87}X + \ldots + C_{90}X^4)Y^2 + \ldots + (C_{96} + C_{97}X + \ldots + C_{100}X^4)Y^4 \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad Y > 0
\end{aligned}$$

$$\tag{8}$$

$F_{ij}(X, Y)$ denotes in fact a function constructed from two polynomials

$$F_{ij}(X,Y) = \begin{cases} F_{ij}^{neg}(X,Y) & \text{for} \quad Y \le 0 \\ F_{ij}^{pos}(X,Y) & \text{for} \quad Y > 0 \end{cases}$$

where the polynomials F_{ij} fulfil the conditions

$$F_{ij}^{neg}(X,Y)_{Y=0} = F_{ij}^{pos}(X,Y)_{Y=0} \qquad\qquad \left(\frac{\partial F_{ij}^{neg}}{\partial Y}\right)_{Y=0} = \left(\frac{\partial P_{ij}^{pos}}{\partial Y}\right)_{Y=0}$$

We have computed 4000 "data points" in the range

$$Z = 6; 13; 29; 47; 74; 92 \qquad 10 \text{ keV} \le T \le 10 \text{ TeV} \qquad 10 \text{ keV} \le k_c \le T$$

and we have performed a least-squares fit to determine the parameters.

The values of the parameters (ξ_σ, α, v_σ, C_i for σ and ξ_l, β, V_l, C for E_{Loss}^{brem}) can be found in the DATA statement within the functions GBRSGE and GBRELE which compute the formula (3) and (4) respectively.

The errors of the parameterisations (3) and (4) can be estimated as

$$
\frac{\Delta\sigma}{\sigma} \;=\; \begin{cases} 12 - 15\% & \text{for} & T \leq 1MeV \\ \leq 5 - 6\% & \text{for} & 1MeV < T \leq 10TeV \end{cases}
$$

$$
\frac{\Delta E_{Loss}^{brem}}{E_{Loss}^{brem}} \;=\; \begin{cases} 10 - 15\% & \text{for} & T \leq 1MeV \\ 5 - 6\% & \text{for} & 1MeV < T \leq 100GeV \\ 10\% & \text{for} & 100GeV < T \leq 10TeV \end{cases}
$$

We have performed a fit to the "data" without the Midgal corrections, too. In this case we used the data of Seltzer and Berger without any correction for $T \leq 10$ GeV and we used the Bethe-Heitler cross-section for $T \geq 10$ GeV. The parameterised forms of the cross-section and energy loss are the same as they were in the first fit (i.e. (3) and (4)), only the numerical values of the parameters have changed. These values are in `DATA` statements in the functions `GBRSGE` and `GBRELE` and this second kind of parameterisation can be activated using the `PATCHY` switch `+USE,BETHE`. (The two parameterisations give different results for high electron energy.)

The energy loss due to soft photon bremsstrahlung is tabulated at initialisation time as a function of the medium and of the energy by routine `GBRELA` (see `JMATE` data structure).

The mean free path for discrete bremsstrahlung is tabuled at initialisation time as a function of the medium and of the energy by routine `GBRSGA` (see `JMATE` data structure).

2.2 Corrections for e^-/e^+ differences

The radiative energy loss for electrons or positrons is:

$$
-\frac{1}{\rho}\left(\frac{dE}{dx}\right)_{rad}^{\pm} \;=\; \frac{N_{Av}\,\alpha r_e^2}{A}(T+m)Z^2\,\Phi_{rad}^{\pm}(Z,T)
$$

$$
\Phi_{rad}^{\pm}(Z,T) \;=\; \frac{1}{\alpha r_e^2 Z^2 (T+m)}\int_0^T k\frac{d\sigma^{\pm}}{dk}dk
$$

Reference [77] says that:

"The differences between the radiative loss of positrons and electrons are considerable and cannot be disregarded.

[...] The ratio of the radiative energy loss for positrons to that for electrons obeys a simple scaling law, [...] is a function only of the quantity T/Z^2 "

In other words:

$$
\eta \;=\; \frac{\Phi_{rad}^{+}(Z,T)}{\Phi_{rad}^{-}(Z,T)} = \eta\left(\frac{T}{Z^2}\right)
$$

The authors have calculated this function in the range $10^{-7} \leq \frac{T}{Z^2} \leq 0.5$ (here the kinetic energy T is expressed in MeV). Their *data* can be fairly accurately reproduced using a parametrisation:

$$
\eta \;=\; \begin{cases} 0 & \text{if} & x \leq -8 \\ \frac{1}{2} + \frac{1}{\pi}\arctan\left(a_1 x + a_3 x^3 + a_5 x^5\right) & \text{if} & -8 < x < 9 \\ 1 & \text{if} & x \geq 9 \end{cases}
$$

where:

$$x = \log\left(C\frac{T}{Z^2}\right) \text{ (T in GeV)}$$

$$C = 7.5221 \times 10^6$$

$$a_1 = 0.415$$

$$a_3 = 0.0021$$

$$a_5 = 0.00054$$

This e^-/e^+ energy loss difference is not a pure low-energy phenomenon (at least for high Z), as it can be seen from Tables 1.2, 1.3 and 1.4.

$\frac{T}{Z^2}(GeV)$	T	η	$\left(\frac{rad.\ loss}{total\ loss}\right)_{e^-}$
10^{-9}	$\sim 7keV$	~ 0.1	$\sim 0\%$
10^{-8}	$67keV$	~ 0.2	$\sim 1\%$
2×10^{-7}	$1.35MeV$	~ 0.5	$\sim 15\%$
2×10^{-6}	$13.5MeV$	~ 0.8	$\sim 60\%$
2×10^{-5}	$135.MeV$	~ 0.95	$> 90\%$

Table 1.2: ratio of the e^-/e^+ radiative energy loss in lead (Z=82).

The scaling holds for the ratio of the total radiative energy losses, but it is significantly broken for the photon spectrum in the screened case. In case of a point Coulomb charge the scaling would hold also for the spectrum. The scaling can be expressed by:

$$\frac{\Phi^+}{\Phi^-} = \eta\left(\frac{T}{Z^2}\right) \qquad\qquad \frac{\frac{d\sigma^+}{dk}}{\frac{d\sigma^-}{dk}} = \text{does not scale}$$

If we consider the photon spectrum from bremsstrahlung reported in [77] we see that:

$$\frac{d\sigma^{\pm}}{dk} = S^{\pm}\left(\frac{k}{T}\right) \qquad \frac{S^+(k)}{S^-(k)} \leq 1 \qquad S^+(1) = 0 \qquad S^-(1) > 0$$

We further assume that:

$$\frac{d\sigma^+}{dk} = f(\epsilon)\frac{d\sigma^-}{dk} \qquad\qquad \epsilon = \frac{k}{T} \qquad\qquad (9)$$

In order to satisfy approximately the scaling law for the ratio of the total radiative energy loss, we require for $f(\epsilon)$:

$$\int_0^1 f(\epsilon)d\epsilon = \eta \qquad\qquad (10)$$

From the photon spectra we require:

$$\left.\begin{array}{l} f(0) = 1 \\ f(1) = 0 \end{array}\right\} \qquad \text{for all } Z, T \qquad\qquad (11)$$

Table 1.4: Difference in the energy loss and bremsstrahlung cross-section for e^-/e^+ in Carbon and Lead with a cut for γ and $e^\pm$ of 1MeV. ΔE_l^0 is the value without the correction for the difference e^-/e^+.

We have chosen a simple function f:

$$f(\epsilon) \quad = \quad C(1 - \epsilon)^\alpha \qquad\qquad C, \alpha > 0 \tag{12}$$

from the conditions (10), (11) we get:

$$C \quad = \quad 1$$
$$\alpha \quad = \quad \frac{1}{\eta} - 1 \qquad (\alpha > 0 \text{ because } \eta < 1)$$
$$f(\epsilon) \quad = \quad (1 - \epsilon)^{\frac{1}{\eta} - 1}$$

We have defined weight factors F_l and F_σ for the positron continuous energy loss and discrete bremsstrahlung cross section:

$$F_l = \frac{1}{\epsilon_0} \int_0^{\epsilon_0} f(\epsilon) d\epsilon \qquad\qquad F_\sigma = \frac{1}{1 - \epsilon_0} \int_{\epsilon_0}^1 f(\epsilon) d\epsilon \tag{13}$$

$$100\frac{E^+_{dep} - E^-_{dep}}{\sqrt{\sigma^2_+ + \sigma^2_-}}(\%)$$

Table 1.5: Difference in the shower development for e^-/e^+ in Carbon and Lead. *No diff* refers to the value without the correction for the difference e^-/e^+.

where $\epsilon_0 = \frac{k_c}{T}$ and k_c is the photon cut BCUTE. In this scheme the positron energy loss and discrete bremsstrahlung can be calculated as:

$$\left(-\frac{dE}{dx}\right)^+ = F_l\left(-\frac{dE}{dx}\right)^- \qquad\qquad \sigma^+_{brems} = F_\sigma \sigma^-_{brems}$$

As in this approximation the photon spectra are identical, the same SUBROUTINE is used for generating e^-/e^+ bremsstrahlung. The following relations hold:

$$
\begin{aligned}
F_\sigma &= \eta(1-\epsilon_0)^{\frac{1}{\eta}-1} < \eta \\
\epsilon_0 F_l + (1-\epsilon_0)F_\sigma &= \eta \qquad\qquad\qquad\qquad \text{from the def (13)} \\
\Rightarrow F_l &= \eta\frac{1-(1-\epsilon_0)^{\frac{1}{\eta}}}{\epsilon_0} > \eta\frac{1-(1-\epsilon_0)}{\epsilon_0} = \eta \qquad \Rightarrow \begin{cases} F_l > \eta \\ F_\sigma < \eta \end{cases}
\end{aligned}
$$

which is consistent with the spectra.

The effect of this e^-/e^+ bremsstrahlung difference can be also seen in e.m. shower development, when the primary energy is not too high. An example can be found in table 1.5.

Simulation of discrete bremsstrahlung by electrons

1 Subroutines

CALL **GBREME**

GBREME generates a bremsstrahlung photon from an electron as a discrete process. The photon energy is sampled from a parameterisation of the bremsstrahlung cross-section of Seltzer and Berger [75] for electron energies below 10 GeV, and from the screened Bethe-Heitler cross-section above 10 GeV. Midgal corrections are applied in both cases. The angular distribution of the photon is calculated by the function GBTETH.

  Input :   via common block /GCTRAK/

  Output: via common block /GCKING/.

GBREME is called from the tracking routine GTELEC when the parent electron reaches a radiation point during tracking.

THETA   = **GBTETH**   (ENER,PARTM,EFRAC)

THETA   (REAL) angle of the radiated photon or $e^{\pm}$ pair;

ENER   (REAL) energy of the particle;

PARTM   (REAL) mass of the particle;

EFRAC   (REAL) ratio between the energy of the photon and the energy of the particle.

GBTETH calculates the angular distribution of the $e^{+}e^{-}$-pair in photon pair production and of the emitted photon in μ and $e^{\pm}$ bremsstrahlung. GBTETH is called by GBREME.

2 Method

The photon energy is sampled according to the Seltzer and Berger bremsstrahlung spectrum [75]. Seltzer and Berger have calculated the spectra for materials with atomic numbers Z = 6,13,29,47,74,92 in the electron (kinetic) energy range 1 keV - 10 GeV. Their tabulated results have been used as input in a parametrising-fitting procedure. The functional form of the parameterisation for the quantity:

$$S(x) = C k \frac{d\sigma}{dk}$$

can be written as

$$S(x) = \begin{cases} (1 - a_h \epsilon)F_1(\delta) + b_h \epsilon^2 F_2(\delta) & T \geq 1 MeV \\ 1 + a_l x + b_l x^2 & T < 1 MeV \end{cases} \qquad (1)$$

where:

C	normalisation constant	k	photon energy
T, E	kinetic and total energy of the primary electron	$x \;=\; \dfrac{k}{T}$	
$\epsilon \;\;=\;\; \dfrac{k}{E} = x\dfrac{T}{E}$			

The $F_i(\delta)$ screening functions depend on the screening variable:

$$
\begin{aligned}
\delta &= \frac{136\,m_e}{Z^{1/3}\,E}\frac{\epsilon}{1-\epsilon} \\
F_1(\delta) &= F_0(42.392 - 7.796\delta + 1.961\delta^2 - F) & \delta \le 1 \\
F_2(\delta) &= F_0(41.734 - 6.484\delta + 1.250\delta^2 - F) & \delta \le 1 \\
F_1(\delta) &= F_2(\delta) = F_0(42.24 - 8.368\ln(\delta + 0.952) - F) & \delta > 1 \\
F_0 &= \frac{1}{42.392 - F} \\
F &= 4\ln Z - 0.55(\ln Z)^2
\end{aligned}
$$

$a_{h,l}$ and $b_{h,l}$ are parameters to be fitted.

The 'high energy' (T > 1 MeV) formula comes from the Coulomb-corrected, sceened Bethe-Heitler formula (see e.g. [78, 10, 12]). However, there are two things in eq. (1) which make a difference:

1. a_h, b_h depend on T and on the atomic number Z (in the case of the Bethe-Heitler spectrum $a_h = 1$, $b_h = 0.75$);

2. the function F is not the same than that in the Bethe-Heitler cross-section, this function gives a better behaviour in the high frequency limit, i.e. when $k \to T$ ($x \to 1$).

The T and Z dependence of the parameters are described by the equations:

$$
\begin{aligned}
a_h &= 1 + \frac{a_{h1}}{u} + \frac{a_{h2}}{u^2} + \frac{a_{h3}}{u^3} \\
b_h &= 0.75 + \frac{b_{h1}}{u} + \frac{b_{h2}}{u^2} + \frac{b_{h3}}{u^3} \\
a_l &= a_{l0} + a_{l1}\,u + a_{l2}\,u^2 \\
b_l &= b_{l0} + b_{l1}\,u + b_{l2}\,u^2
\end{aligned}
$$

with

$$
u = \ln\left(\frac{T}{m_e}\right)
$$

the $a_{hi}, b_{hi}, a_{li}, b_{li}$ parameters are polynomials of second order in the variable:

$$
v = [Z(Z+1)]^{1/3}
$$

It can be seen relatively easily that for the limiting case $T \to \infty$, $a_h \to 1$, $b_h \to 0.75$, so eq. (1) gives the Bethe-Heitler cross section.

There are altogether 36 linear parameter in the formulae , their values are given in GBREME. The parameterisation reproduces the Seltzer-Berger tables within a few % (2-3 % on average, the maximum error being less than 10-12 %), the tables, on the other hand, agree well with the experimental data and theoretical (low- and high-energy) results (less than 10 % below 50 MeV, less than 5 % above 50 MeV).

Apart from the normalisation the cross section differential in photon energy can be written as:

$$
\frac{d\sigma}{dk} = \frac{1}{\ln\frac{1}{x_c}}\frac{1}{x}g(x) = \frac{1}{\ln\frac{1}{x_c}}\frac{1}{x}\frac{S(x)}{S_{max}}
$$

where $x_c = k_c/T$, k_c is the photon cut-off energy below which the bremsstrahlung is treated as a continuous energy loss (this cut is BCUTE in the program). Using this decomposition of the cross section and two random numbers r_1, r_2 uniformly distributed in $]0, 1[$, the sampling of x is done as follows:

1. sample x from

$$\frac{1}{\ln \frac{1}{x_c}} \frac{1}{x} \qquad \text{setting} \qquad x = e^{r_1 \ln x_c}$$

2. calculate the rejection function $g(x)$ and:

   - if $r_2 > g(x)$ reject x and go back to 1;
   - if $r_2 \le g(x)$ accept x.

To apply the Migdal correction [76] all it has to be done is to multiply the rejection function by the Migdal correction factor:

$$C_M(\epsilon) = \frac{1 + C_0/\epsilon_c^2}{1 + C_0/\epsilon^2}$$

where

$$C_0 = \frac{n r_0 \lambdabar^2}{\pi}, \qquad \epsilon_c = \frac{k_c}{E}$$

n electron density in the medium
r_0 classical electron radius
$\lambdabar$ reduced Compton wavelength of the electron.

This correction decreases the cross-section for low photon energy.

After the successful sampling of ϵ, GBREME generates the polar angles of the radiated photon with respect to the parent electron's momentum. It is difficult to find in the literature simple formulas for this angle. For example the double differential cross section reported by Tsai [13, 14] is the following:

$$
\begin{aligned}
\frac{d\sigma}{dk\,d\Omega} &= \frac{2\alpha^2 e^2}{\pi k m^4} \left\{ \left[\frac{2\epsilon - 2}{(1+u^2)^2} + \frac{12 u^2(1-\epsilon)}{(1+u^2)^4} \right] Z(Z+1) \right. \\
&\quad \left. + \left[\frac{2 - 2\epsilon - \epsilon^2}{(1+u^2)^2} - \frac{4u^2(1-\epsilon)}{(1+u^2)^4} \right] \left[X - 2Z^2 f_c((\alpha Z)^2) \right] \right\} \\
u &= \frac{E\theta}{m} \\
X &= \int_{t_{min}}^{m^2(1+u^2)^2} \left[G_Z^{el}(t) + G_Z^{in}(t) \right] \frac{t - t_{min}}{t^2} dt
\end{aligned}
$$

$G_Z^{el,in}(t)$ atomic form factors

$$t_{min} = \left[\frac{k m^2(1+u^2)}{2E(E-k)} \right]^2 = \left[\frac{\epsilon m^2(1+u^2)}{2E(1-\epsilon)} \right]^2$$

This distribution is complicated to sample, and it is anyway only an approximation to within few percent, if nothing else, due to the presence of the atomic form-factors. The angular dependence is contained in the variable $u = E\theta m^{-1}$. For a given value of u the dependence of the shape of the function on Z, E, $\epsilon = k/E$ is very weak. Thus, the distribution can be approximated by a function

$$f(u) = C\left(u e^{-au} + du e^{-3au} \right) \tag{2}$$

where

$$C = \frac{9a^2}{9+d} \qquad a = 0.625 \qquad d = 0.13 \left(0.8 + \frac{1.3}{Z} \right) \left(100 + \frac{1}{E} \right) (1 + \epsilon)$$

where E is in GeV. While this approximation is good at high energies, it becomes less accurate around few MeV. However in that region the ionisation losses dominate over the radiative losses.

The sampling of the function $f(u)$ can be done in the following way (r_i, $i = 1, 2, 3$ are uniformly distributed random numbers in [0,1]):

$$P = \int_{u_{max}}^{\infty} f(u) \, du$$

E (MeV)	P(%)
0.511	3.4
0.6	2.2
0.8	1.2
1.0	0.7
2.0	< 0.1

Table 1.6: Angular sampling efficiency

1. Choose between ue^{-au} and due^{-3au}:

$$b = \begin{cases} a & \text{if} \quad r_1 < 9/(9+d) \\ 3a & \text{if} \quad r_1 \geq 9/(9+d) \end{cases}$$

2. Sample ue^{-bu}:

$$u = -\frac{\log(r_2 r_3)}{b}$$

3. check that:

$$u \leq u_{max} = \frac{E\pi}{m}$$

   otherwise go back to 1.

The probability of failing in the last test is reported in table 1.6.

The function $f(u)$ can be used also to describe the angular distribution of the photon in μ bremsstrahlung and to describe the angular distribution in photon pair production.

The azimuthal angle, Φ, is generated isotropically. This information is used to calculate the momentum vector of the radiated photon, to transform it to the GEANT coordinate system and to store the result into common block /GCKING/. Also, the momentum of the parent electron is updated.

2.1 Restrictions

1. Target materials composed of compounds or mixtures are treated identically to elements using the effective atomic number Z calculated in GSMIXT (this is not correct when computing the mean free path!).

Total cross-section for e^+e^- annihilation

1   Subroutines

CALL **GANNII**

GANNII tabulates the mean free path at initialisation as a function of the medium and of the energy (see JMATE data structure). The energy binning is set within the array ELOW (common block /GCMULO/) in the routine GPHYSI. GANNII is called from GPHYSI.

2   Method

For the annihilation into two photons the cross-section formula of Heitler is used. The total cross-section is given by [12, 79]

$$\sigma_{2\gamma}(Z, E) = \frac{Z \pi r_0^2}{\gamma + 1} \left[\frac{\gamma^2 + 4\gamma + 1}{\gamma^2 - 1} \ln \left(\gamma + \sqrt{\gamma^2 - 1} \right) - \frac{\gamma + 3}{\sqrt{\gamma^2 - 1}} \right] \tag{1}$$
$$r_0 = \text{classical electron radius}$$

For compounds, the cross-section is calculated using an effective atomic number as explained in [PHYS010].

Positrons can annihilate in a single photon if the electron with which it interacts is bound to a nucleus. The total cross-section for such a process is

$$\sigma_{1\gamma}(Z, E) = 4\pi r_0^2 \alpha^4 \frac{Z^5}{\gamma \beta (\gamma + 1)^2} \left[\gamma^2 + \frac{2}{3}\gamma + \frac{4}{3} + \frac{\gamma + 2}{\gamma \beta} \ln(\gamma + \gamma\beta) \right] \tag{2}$$
$$\alpha = \text{fine structure constant}$$

In the derivation of this formula, only the interactions with the K-shell electrons are taken into account. As the cross-section depends on Z^5, a special value of Z_{eff} is computed in GPROBI:

$$Z_{eff} = \sum_i \frac{p_i}{A_i} Z^5 \tag{3}$$

The notation of [PHYS010] is used.

The total cross-section for the positron annihilation is $\sigma = \sigma_{2\gamma} + \sigma_{1\gamma}$. The value of $\sigma_{1\gamma}$ is at it largest for heavy materials, for example, it is ~ 20 % of σ for a positron of 440 keV of kinetic energy in lead. For lower and higher energies the probability is lower.

Simulation of e^+e^- annihilation

1   Subroutines

CALL **GANNI**

`GANNI` generates the annihilation of a positron into either one or two photons. It uses the following input and output:

input: via common /GCTRAK/

output: via common /GCKING/

The routine is called automatically from the tracking routine `GTELEC`, when the positron reaches its interaction point during the tracking.

CALL **GANNIR**

`GANNIR` generates the positron annihilation at rest. It is called from the tracking routine `GTELEC`, if the positron energy is below the cut-off energy `CUTELE` in common block `/GCCUTS/`.

2   Method

The type of annihilation is sampled from the total cross-sections for the annihilation into two photons and into one photon (see section [PHYS350]).

Annihilation into two photons

The differential cross-section of the two-photon positron-electron annihilation can be written as [79, 12]:

$$\frac{d\sigma(Z,\epsilon)}{d\epsilon} = m\,a[S(a\epsilon) + S(a(1-\epsilon))] \tag{1}$$

where m is the electron mass Z is the atomic number of the material. If we indicate with E the initial energy of the positron, with r_0 the classical electron radius and with k the energy of the less energetic photon generated, we have:

$$\gamma = \frac{E}{m} \qquad\qquad a = \gamma + 1$$

$$\epsilon = \frac{k}{E+m} \qquad\qquad S(x) = C_1\left[-1 + \frac{C_2}{x} - \frac{1}{x^2}\right]$$

$$C_1 = \frac{Z\pi r_0^2}{a(E-m)} \qquad\qquad C_2 = a + \frac{e\gamma}{a}$$

The kinematical limits for the variable ϵ are:

$$\epsilon_0 = \frac{1}{a + \sqrt{\gamma^2 - 1}} \leq \epsilon \leq \frac{1}{2}$$

Due to the symmetry of the formula (1) in ϵ, the range of ϵ can be expanded from $(\epsilon_0, 1/2)$ to $(\epsilon_0, 1-\epsilon_0)$ and the second function S can be eliminated from the formula. Having done this, the differential cross-section can be decomposed (apart from the normalisation) as:

$$\frac{d\sigma}{d\epsilon} = \underbrace{\frac{1}{\ln\frac{1-\epsilon_0}{\epsilon_0}}\frac{1}{\epsilon}}_{f(\epsilon)}\underbrace{\frac{(a^2 + 2a - 2) - a^2\epsilon - \frac{1}{\epsilon}}{a^2 - 2}}_{g(\epsilon)} \tag{2}$$
Figure 41: Comparison between the K-shell binding energies given by the expression in the text and the tabulated values.

Using the expression (2) with random numbers $r_i \in]0, 1[, i = 1, 2$, the secondary photon energy is sampled by the following steps:

1. sample ϵ from $f(\epsilon)$:

$$\epsilon = \epsilon_0 \exp\left[\ln\left(\frac{1 - \epsilon_0}{\epsilon_0}\right) r_1\right] \tag{3}$$

2. compute the rejection function $g(\epsilon)$ and

   (a) if $r_2 \leq g(\epsilon)$ accept ϵ
   (b) if $r_1 > g(\epsilon)$ go back to 1.

After the successful sampling of ϵ, the photon energy is computed as

$$k = (E + m)\epsilon \tag{4}$$

and then `GANNI` generates the polar angles of the photon with respect to an axis defined by the momentum of the positron. The azimuthal angle Φ is generated isotropically and Θ is computed from the energy-momentum conservation. With this information, the momentum vector of both photons can be calculated and transformed into the `GEANT` coordinate system.

The routine `GANNIR` treats the special case when a positron falls below the cut-off energy (`CUTELE` in common block `/GCCUTS/`) before annihilating. In this case, it is assumed that the positron comes to rest before annihilating. `GANNIR` generates two photons with energy $k = m$. The angular distribution is isotropic.

Annihilation into one photon

The generated photon is assumed to be collinear with the positron. Its energy will be

$$k = E + m_e - E_{bind} \qquad (5)$$

where E_{bind} is the binding energy of the K-shell electron. It can be estimated as follows

$$E_{bind} = 0.5 (Z\,\alpha)^2\,m_e \qquad (6)$$

where α is the fine stucture constant. The comparison of this expression with the experimental data from [80] is shown in figure 41.

3 Restrictions

1. The annihilation processes producing three or more photons are ignored, because these processes are negligible compared to the annihilation into two photons [12, 54];

2. In calculating the process it is assumed that the atomic electron initially is free and at rest. This is the usual assumption used in shower programs [12];

Synchrotron radiation

1 Subroutines

> CALL **GSYNC**

GSYNC is called for electron and positrons when the flag ISYNC is set > 0. It computes the magnetic field and calls GSYNGE for the generation of the synchrotron radiation photons. It reads them in the GEANT stack. GSYNC is called from GTELEC.

> CALL **GSYNGE** (GAMMA,AMASS,FLDT,STEP,NTR,ETR,STR)

GSYNGE generates the synchrotron radiation for an e$^-$ or e$^+$ with the Lorentz factor GAMMA in the magnetic field FLDT and when the step length is STEP. The number of the secondary photons is NTR, their energy is in the array ETR and their position along the step is in STR. GSYNGE is called by GSYNC.

2 Method

A charged particle in a magnetic field emits radiation. The number of photons emitted in a second is

$$\frac{d^2N}{d\varepsilon\,dt} = \frac{15\sqrt{3}}{8}\frac{P}{\varepsilon_c} \tag{1}$$

where ε_c is the critical photon energy (the median of the energy spectrum) and P the total radiated power:

$$\varepsilon_c = \frac{3}{2}\hbar c\frac{\gamma^3}{\rho} \tag{2}$$

$$P = \frac{2}{3}\frac{e^2 c}{\rho^2}\beta^4\gamma^4 \tag{3}$$

γ is the e$^-$/e$^+$ Lorentz factor E_{tot}/m_e and $\beta = 1 - 1/\gamma^2$. ρ is the curvature caused by the magnetic field. For more detailed derivation of these equations, see [81]. The velocity of the particle being βc, the number of photons per meter is

$$
\begin{aligned}
\frac{d^2N}{d\varepsilon\,dx} &= \frac{d^2N}{d\varepsilon\,dt}\frac{1}{\beta c} \\
&= \frac{5\sqrt{3}}{6}\frac{e^2}{\hbar c}\beta^3\gamma\frac{1}{\rho} \\
&= \frac{5}{2\sqrt{3}}\alpha\frac{\gamma}{\rho} \approx 0.01053\frac{\gamma}{\rho}
\end{aligned} \tag{4}
$$

The fine structure constant $\alpha = e^2/(\hbar c)$ and it is assumed that $\beta^3 \approx 1$.

The curvature in a magnetic field B which has a component $B_\perp$ transversal to the particle velocity can be computed [55]

$$\rho = \frac{p}{0.3\,B_\perp} \tag{5}$$
Figure 42: The point where the synchrotron radiation photon is generated. The figure on the left describes the situation when ISYNC = 1, and the one on the right when ISYNC = 3. The little arrows are the photons and STEP is the step taken by the e^- or e^+. VECT is the new direction computed in GTELEC before entering in GSYNC.

where p is the momentum of the particle in GeV. B is in tesla and ρ is in meters.

Knowing the step length, the energy of the electron and the curvature of the particle track in the magnetic field, the number of photons in a step δx can be sampled from a Poissonian distribution around the mean value

$$\overline{n_{\delta x}} = 0.01053 \frac{\gamma}{\rho} \delta x \tag{6}$$

Now, the energies of $n_{\delta x}$ photons have to be determined. The energy distribution in a step follows the distribution [81]

$$f(\varepsilon) = \frac{dN}{d\varepsilon} \propto \int_{\varepsilon/\varepsilon_c}^{\infty} K_{5/3}(x)\, dx \tag{7}$$

The energy can be sampled from this by inverse transform method:

$$N = F(\varepsilon) = \int f(\varepsilon)\, d\varepsilon \tag{8}$$

$$\varepsilon = F^{-1}(N) \tag{9}$$

The double integral is not analytically solved, and the sampling is done from tabulated values of numerically computes $F(\varepsilon)$.

Two methods have been implemented. If the flag ISYNC is set to 1, the photons are emitted at the end of the step along the current direction. If ISYNC is set to 3, the photons are emitted randomly along the tangent the real trajectory of the particle. In the case when ISYNC = 3, the magnetic field tracking routines are called for each photon, and therefore this option is considerably slower than ISYNC = 1.

Simulation of particle decays in flight

1   Subroutines

CALL **GDECAY**

`GDECAY` is the control routine for the simulation of particle decays in flight. For a given parent particle it selects from a list a two- or three-body decay mode using the known branching ratios and calls the routines needed to generate the vertex and secondary tracks. It used the following input and output:

`input:`   via common blocks `/GCTRAK/` and `/GCKINE/`
`output:` via common block `/GCKING/`

`GDECAY` is called by the tracking routines. It calls the subroutines `GDECA2` for two-body decay, `GDECA3` for three-body decay, `GLOREN` for Lorentz transformation and `GDROT` for rotation. For the documentation of `GLOREN` and `GDROT`, see [`PHYS410`].

CALL **GDECA2**   (XM0,XM1,XM2,PCM)

`XM0`   (`REAL`) mass of the parent particle
`XM1`   (`REAL`) mass of the first decay product
`XM2`   (`REAL`) mass of the second decay product
`PCM(3,4)` (`REAL`) array containing the four-vectors of the decay products

`GDECA2` simulates the two-body decay with isotropic angular distribution in the center-of-mass system. It is called from `GDECAY`.

CALL **GDECA3**   (XM0,XM1,XM2,XM3,PCM)

`XM0`   (`REAL`) mass of the parent particle
`XM1`   (`REAL`) mass of the first decay product
`XM2`   (`REAL`) mass of the second decay product
`XM3`   (`REAL`) mass of the third decay product
`PCM(3,4)` (`REAL`) array containing the four-vectors of the decay products

`GDECA3` simulates the three-body decay with isotropic angular distribution in the center-of-mass system. It is called from `GDECAY`.

2   Method

- Upon entry to `GDECAY` a binary search is made in a list of parent particles. This list is stored in the `JPART` structure and currently contains the particles defined in `GPART` [`CONS300`]. If the current particle cannot be found in the list, control is returned *without* any decay generation. Up to six decay modes and their corresponding branching ratios are then extracted from the `JPART` data banks (see [`CONS310`]).

- A decay channel is selected according to the branching ratios. If the sum of the branching ratios for a particle is not equal 100%, it is possible that *no* decay is selected.

- Depending on whether the two- or three-body decay is selected, either `GDECA2` or `GDECA3` is called to generate the four-momenta of the decay products with isotropic angular distribution in the center-of-mass system.

- The momentum vectors of the decay products are transformed into the laboratory system and rotated back into the `GEANT` coordinate frame. The kinematics of the products is stored in the common `/GCKING/`.

- When a particle decays and no branching ratio is defined, then `GDECAY` calls the user routine `GUDCAY`.

Rotations and Lorentz transformation

1   Subroutines

CALL **GLOREN**   (BETA,PA,PB*)

GLOREN transforms the momentum and the energy from one Lorentz frame (A) to another (B). It uses the following input and output:

BETA(4)   (REAL) velocity components in light units of frame B in frame A, BETA(1...3) = $\vec{\beta}$,
            BETA(4)= $(1 - \beta^2)^{-1/2} = \gamma$;
PA(4)   (REAL) momentum components in the frame (A);
PB(4)   (REAL) momentum components in the frame (B).

GLOREN is called from the routine GDECAY. The momentum $\vec{p}_A$ and energy E_A in reference frame A are transformed into the momentum $\vec{p}_B$ and energy E_B in reference frame B which translates with velocity $\vec{\beta}$ with respect to A:

$$
\begin{aligned}
E_B &= \gamma (E_A - \vec{\beta} \cdot \vec{p}_A) \\
\vec{p}_B &= \vec{p}_A + \gamma \vec{\beta} \left(\frac{\gamma \vec{\beta} \cdot \vec{p}_A}{\gamma + 1} - E_A \right)
\end{aligned}
$$

CALL **GDROT**   (P*,COSTH,SINTH,COSPH,SINPH)

GDROT rotates a vector from one reference system to another.

P(3)   (REAL) vector to rotate, overwritten on output;
COSTH   (REAL) cosine of the polar angle;
SINTH   (REAL) sine of the polar angle;
COSPH   (REAL) cosine of the azimuthal angle;
SINPH   (REAL) sine of the azimuthal angle;

GDROT is called from several routines to rotate a particle from in the center-of-mass system to the GEANT (laboratory) system. The following rotation matrix is used:

$$
\begin{pmatrix} \cos\theta\cos\phi & -\sin\phi & \sin\theta\cos\phi \\ \cos\theta\sin\phi & \cos\phi & \sin\theta\sin\phi \\ -\sin\theta & 0 & \cos\theta \end{pmatrix} = \underbrace{\begin{pmatrix} \cos\phi & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{R_\phi} \underbrace{\begin{pmatrix} \cos\theta & 0 & \sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{pmatrix}}_{R_\theta}
$$

R_θ is a counterclockwise rotation around axis y by an angle θ, and R_ϕ is a counterclockwise rotation around axis z' (rotated by an angle θ from the initial position) by an angle ϕ.

CALL **GFANG**   (P,COSTH*,SINTH*,COSPH*,SINPH*,ROTATE*)

P(3)   (REAL) input direction;
COSTH   (REAL) cosine of the polar angle;

```
SINTH      (REAL) sine of the polar angle;
COSPH      (REAL) cosine of the azimuthal angle;
SINPH      (REAL) sine of the azimuthal angle;
ROTATE     (LOGICAL) rotation flag, the rotation matrix is the unit matrix if ROTATE=.FALSE., i.e.  no
           rotation is needed;
```

Find the sine and cosine of the polar and azimuthal angle of the direction defined by the vector `P`. If `P` is along the z axis, `ROTATE=.FALSE.`.

```
     CALL GVROT   (DCOSIN,PART*)
```

```
PART(3)    (REAL) direction to be rotated, overwritten on output;
DCOSIN(3)  (REAL) direction of the new z axis;
```

Given the direction `PART` in a system of reference O, it returns the same direction in the system of reference where the z axis of O is along `DCOSIN`. This routine is very useful when the θ angle of a secondary particle is sampled in a reference frame where the parent particle moves along the z axis. Then the direction of the secondary product in the `MRS` is returned by `GVROT` if `DCOSIN` is the direction of the parent particle.

A call to `GVROT` is equivalent to the following code:

```
     DIMENSION PART(3), DCOSIN(3)
     LOGICAL ROTATE
     .
     .
     .
     CALL GFANG(DCOSIN,COSTH,SINTH,COSPH,SINPH,ROTATE)
     IF(ROTATE) CALL GDROT(PART,COSTH,SINTH,COSPH,SINPH)
```

with the advantage that inside `GVROT` all calculations are performed in double precision.

Ionisation processes for muons and protons

1   Subroutines

CALL **GDRELA**

GDRELA initialises the ionisation energy-loss tables for different materials and particles. The energy binning is in the array ELOW (/GCMULO/) initialised in the routine GPHYSI. The tables are filled with the quantity dE/dx in GeV cm^{-1}, for elements, mixtures and compounds. A temporary table is also filled, containing additional points for integration, to obtain the range-energy table (see [PHYS010]).

GDRELP computes the ionisation energy loss for protons, and the values are stored in the energy loss table. This value is used for other charged hadrons with scaled energy bin.

GDRELM computes the ionisation energy loss for muons, and sums it in the muon table with the energy loss due to the other processes (bremsstrahlung, pair production and nuclear interactions).

The following pointers are used:

JMA = LQ(JMATE-I)   Ith material bank;
JEL1 = LQ(JMA-1) dE/dx for e$^+$/e$^-$(see [PHYS330]);
JEL2 = LQ(JMA-2) dE/dx for μ^+/μ^-;
JEL3 = LQ(JMA-3) dE/dx for protons (used also for other charged particles).

GDRELA is called during initialisation by GPHYSI.

CALL **GDRELP**   (A,Z,DENS,T,DEDX*)

GDRELP computes the ionisation energy loss for protons. It is called by the routine GDRELA. See GDRELX below for the meaning of the parameters.

CALL **GDRELM**   (A,Z,DENS,T,DEDX*)

GDRELM computes the energy loss due to ionisation for muons. It is called by the routine GDRELA. See GDRELX below for the meaning of the parameters.

CALL **GDRELX**   (A,Z,DENS,T,HMASS,DEDX*)

A   (REAL) mass number of the material;
Z   (REAL) atomic number of the material;
DENS   (REAL) density of the material in g cm^{-3}; it is only used to calculate the density correction in case of high values of T;
T   (REAL) kinetic energy of the particle in GeV;
HMASS   (REAL) mass of the particle;
DEDX   (REAL) energy loss of the particle in GeV cm^2 g^{-1}.

This routine calculates the ionisation energy loss for a muon or a proton. It is called by GDRELM and GDRELP.

CALL **GDRSGA**

CDRSGA calculates the total cross-section for the production of δ-rays by electrons (Möller scattering), positrons (Bhabha scattering) and muons. For hadrons, this value is calculated at tracking time. The mean free path as a function of the energy is stored for every medium. The following pointers are used:

```
JMA = LQ(JMATE-I)      pointer to the I^{th} material;
JDRAY = LQ(JMA-11)     δ-ray cross-section for electrons;
JDRAY+NEK1             δ-ray cross-section for positrons;
JDRAY+2*NEK1           δ-ray cross-section for muons.
```

The routine is called during initialisation by `GPHYSI`.

2 Method

In `GEANT`, δ-rays are generated only above a threshold energy T_{cut} which corresponds to the variable `DCUTE` for electrons and positrons, `DCUTM` for all other charged particles. The total cross-section for the production of a δ-ray electron of kinetic energy $T > T_{cut} =$`DCUTE`, `DCUTM` by a particle of kinetic energy E is:

$$\sigma(E, T_{cut}) = \int_{T_{cut}}^{T_{max}} \frac{d\sigma(E, T)}{dT} dT \tag{1}$$

where T_{max} is the maximum energy transferable to the free electron:

$$T_{max} = \frac{2m(\gamma^2 - 1)}{1 + 2\gamma \frac{m}{M} + \left(\frac{m}{M}\right)^2} \tag{2}$$

The energy lost in ionising collisions producing δ-rays below T_{cut} are included in the continuous energy loss. The mean value of the energy lost due to these *soft* collisions is:

$$E_{loss}(E, T_{cut}) = \int_{0}^{T_{cut}} T \frac{d\sigma(E, T)}{dT} dT \tag{3}$$

where m is the electron mass and M is the mass of the incident particle.

In this chapter, the method of calculation of the continuous energy loss and the total cross-section are explained. The generation of δ-rays is explained in chapter [PHYS331].

2.1 Continuous energy loss

The integration of (3) leads to the Bethe-Block stopping power or to the restricted energy loss formula [55]:

$$\frac{1}{\rho}\left(\frac{dE}{dx}\right) = \begin{cases} D\dfrac{ZZ_{inc}^2}{A\beta^2}\left[\ln\left(\dfrac{2m_e\beta^2\gamma^2 T_{max}}{I^2}\right) - 2\beta^2 - \delta - \dfrac{2C_e}{Z}\right] & \text{if } T_{cut} \geq T_{max} \\[4mm] D\dfrac{ZZ_{inc}^2}{A\beta^2}\left[\ln\left(\dfrac{2m_e\beta^2\gamma^2 T_c}{I^2}\right) - \beta^2\left(1 + \dfrac{T_c}{T_{max}}\right) - \delta - \dfrac{2C_e}{Z}\right] & \text{if } T_{cut} < T_{max} \end{cases} \tag{4}$$

where,

D	$2\pi N_A r_e^2 m c^2 = 0.000153537\,\text{GeV cm}^2\,\text{g}^{-1}$	Z	atomic number of medium
A	mass number	ρ	density of medium
T_c	$\min(T_{cut}, T_{max})$	m_e	electron mass

and I is the average ionisation potential of the atom in question. There exists a variety of phenomenological approximations for this. In former versions of `GEANT` the formula quoted by [82] was used ($I = 16\,Z^{0.9}$ eV). At present the values recommended by [83] are used. The ionisation potential I only enters into the logarithmic term of the energy loss formula, but it has been verified that the new parameterisation gives better accuracy especially in the case of high Z. It should be noted that this is not the value of I which is stored in the material data structure by `GPROBI`, which is still calculated as $I = 16\,Z^{0.9}$ eV.

Note: the ionisation potential I must not be changed blindly, hoping that the most up-to-date values give the better results. The value of I is closely connected to the shell correction term (see later).

δ is a correction term which takes account of the reduction in energy loss due to the so-called density effect. This becomes important at high energy because media have a tendency to become polarised as the incident particle velocity increases. As a consequence, the atoms in a medium can no longer be considered as isolated. To correct for this effect the formulation of Sternheimer [84, 85] is used:

$$\delta = \begin{cases} 0 & \text{if} \quad X < X_0 \\ 4.606\,X + C + a(X_1 - X)^m & \text{if} \quad X_0 \leq X < X_1 \\ 4.606\,X + C & \text{if} \quad X \geq X_1 \end{cases} \tag{5}$$

where the medium-dependent constants are calculated as follows:

$$
\begin{aligned}
X &= \log_{10}(\gamma\beta) = \ln(\gamma^2\beta^2)/4.606 & \nu_p &= \sqrt{\frac{N_{el}e^2}{\pi m}} \quad \text{s}^{-1} \text{ plasma frequency} \\
N_{el} &= \frac{\rho Z N_{Av}}{A} \quad \text{electrons cm}^{-3} & C &= -2\ln\left(\frac{I}{h\nu_p}\right) - 1 \\
a &= \frac{4.606(X_a - X_0)}{(X_1 - X_0)^m} & 4.606\,X_a &= -C
\end{aligned}
$$

For condensed media we have:

$$
I < 100 \text{ eV} \quad
\begin{cases}
X_0 &= \begin{cases} 0.2 & \text{if} \quad -C \leq 3.681 \\ -0.326C - 1.0 & \text{if} \quad -C > 3.681 \end{cases} \\
X_1 &= 2.0 \\
m &= 3.0
\end{cases}
$$

$$
I \geq 100 \text{ eV} \quad
\begin{cases}
X_0 &= \begin{cases} 0.2 & \text{if} \quad -C \leq 5.215 \\ -0.326C - 1.5 & \text{if} \quad -C > 5.215 \end{cases} \\
X_1 &= 3.0 \\
m &= 3.0
\end{cases}
$$

and in the case of gaseous media $m = 3$ and:

$$
\begin{aligned}
X_0 &= 1.6 & X_1 &= 4 & \text{for} & \quad C \leq 9.5 \\
X_0 &= 1.7 & X_1 &= 4 & \text{for} & \quad 9.5 < C \leq 10 \\
X_0 &= 1.8 & X_1 &= 4 & \text{for} & \quad 10 < C \leq 10.5 \\
X_0 &= 1.9 & X_1 &= 4 & \text{for} & \quad 10.5 < C \leq 11 \\

X_0 &= 0.326C - 2.5 & X_1 &= 5 & \text{for} & \quad 13.804 < C
\end{aligned}
$$

C_e/Z is a so-called *shell correction term* which accounts for the fact that, at low energies for light elements and at all energies for heavy ones, the probability of collision with the electrons of the inner atomic shells (K, L, etc.) is negligible. The semi-empirical formula used in GEANT, applicable to all materials, is due to Barkas [86]:

$$
\begin{aligned}
C_e(I, \eta) &= (0.42237\eta^{-2} + 0.0304\eta^{-4} - 0.00038\eta^{-6})10^{-6}I^2 \\
&+ (3.858\eta^{-2} - 0.1668\eta^{-4} + 0.00158\eta^{-6})10^{-9}I^3 \\
\eta &= \gamma\beta
\end{aligned}
$$

C_e is a dimensionless constant, but as I in the original article was expressed in eV and in GEANT it is expressed in GeV, the exponent of ten in the I^2-term is $10^{-6+2\times9} = 10^{12}$, and that of the I^3-term is $10^{-9+3\times9} = 10^{18}$.)

experiment	A [89]	B [90]	C [91]

N° of pts with $|\Delta| < 1\sigma$	94	50	8
$\quad\;\; |\Delta| < 2\sigma$	114	52	13
$\quad\;\; |\Delta| < 3\sigma$	119	52	14
$\quad\;\; |\Delta| < 4\sigma$	121	52	15

Table 1.7: Test of `GDRELP` with low energy protons.

This formula breaks down at low energies, and it only applies for values of $\eta > 0.13$ (i.e. $T > 7.9$ MeV for a proton). For $\eta \leq 0.13$ the shell correction term is calculated as:

$$C_e(I, \eta)\Big|_{\eta \leq 0.13} = C_e(I, \eta = 0.13)\frac{\ln\left(\frac{T}{T_{2l}}\right)}{\ln\left(\frac{7.9\,10^{-3}\,GeV}{T_{2l}}\right)}$$

i.e. the correction is *switched off* logarithmically from $T = 7.9$ MeV to $T = T_{2l} = 2$ MeV. `GDRELX` has been tested for protons against energy loss tables [87, 88] for various materials in the energy range 50 MeV-25 GeV. Typical discrepancies are as follows:

Beryllium:	1.1% at 0.05 GeV	0.02% at 25 GeV
Hydrogen :	1.5% at 0.05 GeV	12.1% at 25 GeV
Water :	8.1% at 0.05 GeV	4.4% at 6 GeV

The mean energy loss can be described by the Bethe-Bloch formula (4) only if the projectile velocity is larger than that of orbital electrons. In the low-energy region where this is not verified, a different kind of parameterisation has been chosen [83]:

$$\frac{1}{\rho}\frac{dE}{dx} = \begin{cases} I: & C_1\tau^{\frac{1}{2}} & \text{for} \quad 0 \leq T \leq T_{1l} = 10\,\text{keV} \\ II: & \dfrac{S_L \times S_H}{S_L - S_H} & \text{for} \quad T_{1l} < T \leq T_{2l} = 2\,\text{MeV} \\ III: & \{\text{Bethe-Bloch}\}\left(1 + \dfrac{\nu}{T}\right) & \text{for} \quad T_{2l} < T \end{cases}$$

where

$$S_L = C_2\tau^{0.45} \qquad S_H = \frac{C_3}{\tau}\ln\left[1 + \frac{C_4}{\tau} + C_5\tau\right]$$

$$\tau = \frac{T}{M_p} \qquad M_p = \text{proton mass}$$

Table 1.9: The minimum stopping power calculated from the formula used is compared with values from the tables.

The formula used in the region $T > T_{2l}$ ensures the continuity of the energy loss function at $T = T_{2l}$ when the Bethe-Bloch formula and the parameterisation meet. The parameter ν is chosen in such a way that:

$$\frac{1}{\rho}\frac{dE^{II}}{dx}\bigg|_{T=T_{2l}} = \frac{1}{\rho}\frac{dE^{III}}{dx}\bigg|_{T=T_{2l}}$$

The routine GDRELP calculates the stopping power or restricted energy loss only for $T > T_{2l}$; below this kinetic energy it gives the stopping power (i.e. total energy loss) irrespectively of the value of T_{cut}. This approximation does not introduce a serious source of error since, in the case of a proton, at $T = T_{2l}$ the maximum energy transferable to the atomic electron is $T_{max} \approx 4$ keV, and the restricted loss should be calculated only if $T_{cut} < T_{max}$.

GDRELP has been tested against experimental data and energy loss tables. Some of the test results are summarised in tables 2.1, 2.1 and 2.1.

The energy lost due to the soft δ-rays is tabulated during initialisation as a function of the medium and of the energy by routine GDRELA

The tables are filled with the quantity dE/dx in GeV cm^{-1} (formula (4) above). For a molecule or a mixture the following formula is used:

$$\frac{dE}{dx} = \rho \sum_i p_i \left(\frac{dE}{dX}\right)_i \tag{6}$$

where x is in cm, X in g cm^{-2} and p_i is the proportion by weight of the Ith element.

The energy loss of all charged particles other than electrons, positrons and muons is obtained from that of protons by calculating the kinetic energy of a proton with the same β, and using this value to interpolate the tables:

$$T_{proton} = \frac{M_p}{M}T \tag{7}$$

2.2   Total cross-section

The integration of formula (1) gives the total cross-section :

$$\sigma(Z, E, T_{cut}) = \begin{cases} 2\pi r_0^2 m \dfrac{Z}{\beta^2} \dfrac{1 - Y + \beta^2 Y \ln Y}{T_{cut}} & \text{for spin-0 particles} \\[4mm] 2\pi r_0^2 m \dfrac{Z}{\beta^2} \left(\dfrac{1 - Y + \beta^2 Y \ln Y}{T_{cut}} + \dfrac{T_{max} - T_{cut}}{2E^2} \right) & \text{for spin-}\dfrac{1}{2}\text{ particles} \end{cases} \tag{8}$$

The mean free path is tabulated during initialisation as a function of the medium and of the energy by the routine `GDRSGA` *for leptons only*.

The cross-section (8) is strongly dependent on the mass of the incident particle, and cannot be tabulated in a general way for any charged hadrons. Therefore, for such particles, the cross-section is computed at tracking time in the routine `GTHADR`.

Ionisation processes for heavy ions

1   Subroutines

For a description of the subroutines used to calculate the energy loss tables for protons, see [PHYS430].

    CALL **GTHION**

GTHION transports heavy ions ($A, Z > 1$, particle type 8). For the moment the only discrete processes activated are δ-ray and Čerenkov photon generation.

2   Method

The mean energy loss of the heavy ions can be expressed as:

$$\Delta E = Q^2 S_p \left(\frac{T}{A}\right) \rho t \tag{1}$$

where

Q charge of the ion;

$S_p\left(\dfrac{T}{A}\right)$ energy loss by the a proton with kinetic energy $T_p = T/A$;

T, A kinetic energy and mass number of the ion;

ρ density of the medium;

t step length

This formula is used to calculate the ionisation loss for all the charged hadrons.

In the case of ions, the charge of the ion makes the problem more difficult. Electron-exchange processes with the atoms change the charge as the ion traverses the medium. The main features of this process can be summarised as follows:

- Q loses the dependence on the initial ion charge after a very short initial step, usually $\ll 1\mu$ for condensed media;

- Q does depend on the velocity of the ion;

- even in the case of constant velocity, Q fluctuates around a mean value;

- Q features a small dependence on the medium, especially for small values of T.

If we want to calculate the energy loss of the ion, we need a good parametrisation for the quantity $Q = Q_{eff}$. We give here a relatively simple parametrisation [83, 93]:

$$
\begin{aligned}
Q_{eff} &= Z_I \left[1 - \left(1.034 - 0.1777 e^{-0.08114 Z_I}\right) e^{-v}\right] \\
v &= 121.4139 \frac{\beta}{Z_I^{2/3}} + 0.0378 \sin\left(190.7165 \frac{\beta}{Z_I^{2/3}}\right)
\end{aligned}
\tag{2}
$$

where β is the velocity and Z_I the atomic number of the ion (i.e. the charge of the bare nucleus).

It can be seen that (2) neglects the (small) medium dependence of Q_{eff}. For very high energies ($\beta \to 1$) $Q_{eff} \to Z_I$. For very low energies ($T/A \sim$ few keV) the formula breaks down. Q_{eff} can even become

T/A	He ions	Pb ions
MeV	error (%)	error (%)
10	3	1
5	4	3
3	10	4

Table 1.10: Comparison of the measured and calculated ΔE for 10 MeV/A ions in Pb

29.75							620	4	69	-26	598	93
39.70	2320	1	138	-28	2300	191	550	4	68	-24	528	90

Table 1.11: Comparison of the measured and calculated ΔE and FWHM for O ions in Al; errors are in percent.

negative for $T/A < 20$ keV and $Z_I > 20$. However this is not a serious source of error when calculating ΔE, since in this case the range of the ion is very small, and it can almost be said that it stops *immediately*.

The calculation of the energy loss straggling (fluctuations) differs from that of *normal* charged hadrons. For the charged hadrons the fluctuations come from the statistical nature of the projectile-atom interactions; for the ions there is another process which broadens the energy loss distribution: the fluctuation of the charge. For heavier ions this process dominates the energy loss straggling for $T/A \leq 10$ MeV.

The heavy ions are in the *Gaussian regime* (see [PHYS332]) of the collisional fluctuations even in the case of very thin absorbers. If T/A is not too high, the σ^2 of the distribution:

$$\sigma^2_{coll} = D \frac{Q^2_{eff} Z}{A} \rho\, t\, m \left[1 + \frac{T_A}{M_u} + \frac{1}{2} \left(\frac{T_A}{M_u} \right)^2 \right]$$ (3)

where

D	$0.307 \dfrac{\text{MeV cm}^2}{\text{g}}$;
T_A	$\dfrac{T}{A}$;
M_u	atomic mass unit;
Z	atomic number of the medium;
A	mass number of the medium.

Analysing the experimental straggling data it is possible to find that the electron-exchange charge fluctuations can be described by a Gaussian with width:

$$\sigma^2_{ch} = D \frac{Q^2_{eff} Z}{A} \rho\, t\, m \frac{C}{2} \left(1 - \frac{Q_{eff}}{Z_I} \right)$$ (4)

where the parameter $C \sim 2.5$ has been derived from the experimental straggling data.

If $Q_{eff} \rightarrow Z_I$, which is the case for high energy heavy ions and for few MeV/A He ions, then $\sigma^2_{ch} \rightarrow 0$.
Figure 43: Stopping powers in Carbon

1.2	162.0	2.37	2.0	168.0	2.95	2.8			

Table 1.12: Comparison of the measured and calculated and FWHM for 1.4 MeV/A Pb ions in gas.

Comparing equations (3) and (4) it can be seen that for heavy ions and for $T/A \ll M_u$ $\sigma_{ch}^2 > \sigma_{coll}^2$. The total energy loss fluctuation can be described by a Gaussian distribution with:

$$\sigma^2 = \sigma_{ch}^2 + \sigma_{coll}^2 \tag{5}$$

The mean energy loss and energy loss fluctuation calculation is performed in the routine `GTHION`, making use of the proton energy loss tables.

Note: The Gaussian fluctuation gives too broad a distribution for high energy in the case of thin absorbers. A correction has been introduced in `GTHION` which cures this discrepancy. In the absence of high energy straggling data for ions, the correction has been tuned using high energy π energy loss data, where the π has been tracked by `GTHION`.

3   Comparison with data

3.1   Mean energy loss and range

A test has been made against the distributions reported in [94] for He ions at 1 and 10 MeV/A and for O and Pb ions at 1, 10 and 100 MeV/A in carbon and the results were found to be correct within 5% both for

He ions in Ar (energies in keV)			
	MonteCarlo		data
t (cm)	ΔE	FWHM	FWHM
0.5	444	38	$\sim$40
1.0	913	53	$\sim$60
2.0	1940	78	$\sim$80

Table 1.13: Comparison of the measured and calculated and FWHM for 1.4 MeV/A He ions in gas.

the energy loss and the range.
Figure 44: Stopping powers in Lead

Another comparison has been made with the tables of [95] for 10 MeV/A ions in lead, with the results shown in table 2. Another comparison with the same tables is shown in Figs. 43 and 44.

A comparison with the tables in [83, 93] for T/A < 1 MeV/A gives an error on $(dE/dx) \leq 10 - 20\%$.

3.2 Comparison of FWHM

A comparison has been made with low energy data ($0.3 \leq T/A \leq 2.5$ MeV/A) in very thin absorbers (1,7 μm, 0.4 μm). Data are taken from the tables in [96] for energy loss of O ions in Al, and the results are reported in table 2. The quoted experimental error for these data is 1% statistical $+ 5\%$ systematic for 417 μg cm^{-2} data and 2% statistical $+ 10\%$ systematic for 110 μg cm^{-2} data.

Plots of energy deposition distributions of 1.4 MeV/A lead and helium ions in gases can be found in [97]. From these we have measured the FWHM and compared them with the ones given by the MonteCarlo. The results can be seen in table 2 and 3.1. It should be noted that the absorber thickness of, for example, Ar compares with that of the preceding case (0.2 cm Ar = 356 μg cm^{-2} and 1.2 cm Ar = 2136 μg cm^{-2}).

Similar comparison has been made for C ions of energies 17.1 and 39.4 MeV in isobuthane [98] and the agreement between data and `GEANT` for FWHM is within 30%.

Total cross-section and energy loss for bremsstrahlung by Muons

1   Subroutines

CALL **GBRELA**

GBRELA fills the tables for continuous energy loss of electrons, positrons and muons due to bremsstrahlung during initialisation time. The energy binning is determined by the array `ELOW` (common `/CGMULO/`) in the routine `GPHYSI`. In the tables, the dE/dx due to bremsstrahlung is summed with that due to the ionisation. For energy loss of muons, `GBRELA` calls the function `GDRELM`. The following pointers are used:

`JMA = LQ(JMATE-I)`   pointer to the Ith material;
`JEL1 = LQ(JMA-1)`   pointer to dE/dx for electrons;
`JEL1+NEK1`   pointer to dE/dx for positrons;
`JEL2 = LQ(JMA-2)`   pointer to dE/dx for electrons.

GBRELA is called by `GPHYSI`.

VALUE   = **GBRELM**   (Z,T,BCUT)

`Z`   (`REAL`) atomic number of the material;
`T`   (`REAL`) kinetic energy of the muon;
`BCUT`   (`REAL`) *soft* bremsstrahlung cut.

GBRELM calculates the muon energy loss due to bremsstrahlung of photons with energy below `BCUT`, (variable `BCUTM` in the common `/GCCUTS/`). Above this value, the bremsstrahlung process is simulated explicitly (see [`PHYS441`]) and the energy lost by the muons is not included in the tables. In the tables, the dE/dx due to bremsstrahlung is summed with the energy lost coming from ionisation, pair production and nuclear interaction. GBRELM is called by GBRELA.

CALL **GBRSGA**

GBRSGA calculates the total cross-section for bremsstrahlung. It tabulates the mean free path in cm as a function of the medium and the energy. The energy binning is determined by the array `ELOW` (common `/CGMULO/`). The following pointers are used:

`JMA = LQ(JMATE-I)`   pointer to the Ith material;
`JBREM = LQ(JMA-9)`   pointer to bremsstrahlung cross-sections;
`JBREM`   pointer for e^-;
`JBREM+NEK1`   pointer for e^+;
`JBREM+2*NEK1`   pointer for μ^+/μ^-.

GBRSGA is called during initialisation by `GPHYSI`.

VALUE   = **GBRSGM**   (Z,T,BCUT)

`Z`   (`REAL`) atomic number of the materian;
`T`   (`REAL`) kinetic energy of the muon;
`BCUT`   (`REAL`) *soft* bremsstrahlung cut.

GBRSGM calculates the total bremsstrahlung cross-section for muons when the emitted photon has an energy greater than `BCUT`, (variable `BCUTM` in the common `/GCCUTS/`). It is called by GBRSGA.

2 Method

The mean value of the energy lost by the muon due to bremsstrahlung of photons of energy $< k_c =$ BCUTM is:

$$E_{loss}^{brem}(Z, T, k_c) = \int_0^{k_c} k \frac{d\sigma(Z, T, k)}{dk} dk \qquad (1)$$

and the total cross-section for the emission of a photon of energy $> k_c$ is

$$\sigma(Z, T, k_c) = \int_{k_c}^{T} \frac{d\sigma(Z, T, k)}{dk} dk \qquad (2)$$

Accurate cross-section formula for the high energy ($T \geq 1$ GeV) muon bremsstrahlung can be found in [99].

2.1 Parameterisation of energy loss and total cross-section

The cross-sections from [99] have been used to calculate *data* points for (1) and (2). These have been parameterised as:

$$\sigma(Z, T, k_c) = Z[Z + \xi_\sigma(1 + \gamma \ln Z)] \left[\ln \frac{k_{max}}{k_c}\right]^\alpha F_\sigma(Z, X, Y) \quad \text{in barn}$$

$$E_{loss}^{brem}(Z, T, k_c) = Z[Z + \xi_l(1 + \delta \ln Z)] \left[\ln \frac{k_c}{E}\right]^\beta F_l(Z, X, Y) \quad \text{in GeV barn}$$

$$k_{max} = E - 0.75\sqrt{e}m_\mu Z^{1/3} \qquad X = \ln \frac{E}{m_\mu}$$

$$Y = \ln \frac{k_c}{m_\mu} \qquad E = T + m_\mu$$

where k_{max} is the maximum possible value of the photon energy. The functions $F_i(Z, X, Y)$ ($i = \sigma, l$) are polynomials:

$$\begin{aligned}
F_i(Z, X, Y) &= (C_1 + C_2 X + \cdots + C_6 X^5) + (C_7 + C_8 X + \cdots + C_{12} X^5)Y \\
&+ \cdots + (C_{31} + C_{32} X + \cdots + C_{36} X^5)Y^5 \\
&+ Z[(C_{37} + C_{38} X + \cdots + C_{40} X^3) + (C_{41} + C_{42} X + \cdots + C_{44} X^3)Y \\
&+ \cdots + (C_{48} + C_{49} X + \cdots + C_{52} X^3)Y^3)]
\end{aligned} \qquad (3)$$

A least-squares fit has been performed on more than 2000 points for $Z = 1, 6, 13, 26, 50, 82, 92$ and 1 GeV $\leq T \leq 10$ TeV and 10 keV $\leq k_c \leq T$. The resulting values of $\xi_{\sigma,l}, \gamma, \alpha, C_i, \xi_l, \delta$ and β can be found in the DATA statements within the functions GBRSGM and GBRELM which compute formulae (1) and (2) respectively. The accuracy of the fit can be estimated as:

$$\frac{\Delta\sigma}{\sigma} = \begin{cases} 10 - 12\% & \text{if } T \leq 5 \text{ GeV} \\ \leq 4\% & \text{if } T > 5 \text{ GeV} \end{cases}$$

$$\frac{\Delta E_{loss}^{brem}}{E_{loss}^{brem}} = \begin{cases} 10\% & \text{if } T \leq 5 \text{ GeV} \\ \leq 3\% & \text{if } T > 5 \text{ GeV} \end{cases}$$

The contribution of the bremsstrahlung to the total energy loss of the muons is less than 1% for $T \leq 5$ GeV. When $k_c \geq k_{max}$, a parameterisation different from (3) can be used for the total muon energy loss due to bremsstrahlung:

$$\begin{aligned}
E_{loss}^{brem}(Z, T) &= E_{loss}^{brem}(Z, T, k = k_{max}) \\
&= Z(Z + 1)k_{max}[d_1 + (d_2 X + d_3 Y) + (d_4 X^2 + d_5 XY + d_6 Y^2) \\
&+ \cdots + (d_{22} X^6 + d_{23} X^5 Y + \cdots + d_{28} Y^6)]
\end{aligned} \qquad (4)$$

where $Y = Z^{1/3}$. The accuracy of the formula (4) for $1 \leq Z \leq 100$ is rather good:

$$\frac{\Delta E_{loss}^{brem}}{E_{loss}^{brem}} = \begin{cases} \leq 1.5\% & \text{if} \quad T > 1 \text{ GeV} \\ \leq 1\% & \text{if} \quad T > 5 \text{ GeV} \end{cases}$$

Simulation of discrete bremsstrahlung by muons

1   Subroutines

CALL **GBREMM**

`GBREMM` generates a photon from bremsstrahlung of a highly energetic muon as a discrete process. For the angular distribution of the photon, is calls the function `GBTETH`.

Input: via common `/GCTRAK/`;
Output: via common `/GCKING/`.

`GBREMM` is called from the tracking routine `GTMUON` when the muon reaches its radiation point during the tracking stage of `GEANT`.

VALUE   = **GBTETH**   (ENER,PARTM,EFRAC)

ENER   (REAL) kinetic energy of the muon;
PARTM   (REAL) mass of the radiating particle (m_μ in this case);
EFRAC   (REAL) ratio of the energy of the radiated photon to the energy of the muon.

`GBTETH` calculates the angular distribution of the $e^- e^+$ pair in photon pair production and of the photon in bremsstrahlung. In case of bremsstrahlung it gives the scaled angle ($\eta = E\theta m^{-1}$) of the photon.

2   Method

The differential cross-section for the emission of a photon of energy k by a muon of energy E is [99, 100]:

$$\frac{d\sigma}{dv} = \frac{N}{v} \left(\frac{4}{3} - \frac{4}{3}v + v^2 \right) \Phi(\delta) \tag{1}$$

where

$$N = \text{normalisation factor} \qquad v = \frac{k}{E}$$

$$\delta = \frac{m_\mu^2}{2E}\frac{v}{1-v} \qquad\qquad e = 2.718\ldots$$

$$\Phi(\delta) = \begin{cases} \ln\left(\frac{189 m_\mu}{m_e Z^{1/3}}\right) - \ln\left(\frac{189\sqrt{e}}{m_e Z^{1/3}}\delta + 1\right) & \text{if } Z \leq 10 \\[2ex] \ln\left(\frac{189 m_\mu}{m_e Z^{1/3}}\right) - \ln\left(\frac{189\sqrt{e}}{m_e Z^{1/3}}\delta + 1\right) + \ln\left(\frac{2}{3}Z^{-1/3}\right) & \text{if } Z > 10 \end{cases}$$

$$v_c = \frac{k_c}{E} \leq v \leq \left(1 - 0.75\sqrt{e}\frac{m_\mu}{E}Z^{1/3} \right) = v_{max}$$

Therefore, the differential cross-section can be written as

$$\frac{d\sigma}{dv} = f(v)g(v) \tag{2}$$

303   PHYS441 – 1

with

$$f(v) = \left[v \ln \left(\frac{v_{max}}{v_c} \right) \right]^{-1}$$

$$g(v) = \frac{1}{\Phi(0)} \left(1 - v + \frac{3}{4} v^2 \right) \Phi(\delta)$$

We can sample the photon energy in the following way (r_1, r_2 uniformly distributed random numbers in $]0, 1[$):

1. sample v:

$$v = v_c \left(\frac{v_{max}}{v_c} \right)^{r_1}$$

2. compute the rejection function $g(v)$ and:

   (a) if $r_2 > g(v)$ go back to step 1

   (b) if $r_2 \leq g(v)$, accept v and $k = vE$.

After the successful sampling of k, GBREMM generates the polar angles of the radiated photon with respect to an axis defined along the parent muon's momentum calling GBTETH. For more information on the sampling procedure see [PHYS341].

Total cross-section and energy loss for $e^- e^+$-pair production by muons

1 Subroutines

> CALL **GPRELA**

`GPRELA` adds to the muon energy loss tables the contribution due to μ-nucleus interactions and e^+e^--pair production in which the energy of the pair is below threshold (see later). For the contribution of pair production, it calls the function `GPRELM`. The energy binning is in the array `ELOW` (common `/CGMULO/`). The following pointers are used:

`JMA = LQ(JMATE-I)`	pointer to the Ith material;
`JEL2 = LQ(JMA-2)`	pointer to dE/dx for $\mu^+\mu^-$.

`GPRELA` is called during initialisation by `GPHYSI`.

> VALUE = **GPRELM** (Z,T,CUT)

`Z`	(`REAL`) atomic number of the material;
`T`	(`REAL`) kinetic energy of the muon;
`CUT`	(`REAL`) maximum energy for the pair considered by the routine.

`GPRELM` calculates the energy loss due to the direct production by muons of $e^- e^+$ pairs with energy below `CUT` (`PPCUTM` in common `/GCCUTS/`). Above this cut, the direct pairs are produced as discrete processes (see [PHYS451]). `GPRELM` is called by `GPRELA`.

> CALL **GPRSGA**

`GPRSGA` calculates the total cross-section for the pair production by photons and the direct pair production by muons. It tabulates the mean free path in cm as a function of medium and energy. For the direct pair production of muons, it calls the function `GPRSGM`. The energy binning is in the array `ELOW` (common `/CGMULO/`). The following pointers are used:

`JMA = LQ(JMATE-I)`	pointer to the Ith material;
`JPAIR = LQ(JMA-10)`	pointer to photon pair production cross-sections;
`JPAIR+NEK1`	pointer to muon pair production.

`GPRSGA` is called during initialisation by `GPHYSI`.

> VALUE = **GPRSGM** (Z,T,CUT)

`Z`	(`REAL`) atomic number of the medium;
`T`	(`REAL`) kinetic energy of the muon;
`CUT`	(`REAL`) minimum energy for the $e^- e^+$ pair.

`GPRSGM` calculates the total cross-section for muon direct pair production where the energy of the pair is greater than `CUT` (`PPCUTM` in common `/GCCUTS/`). It is called by `GPRSGA` (see [PHYS451]).

2 Method

When a muon of energy E moves in the field of an atom of charge Z, it can radiate a e^+e^--pair (4th order QED process) with differential cross-section [99]:

$$\frac{\partial^2 \sigma}{\partial \nu\, \partial \rho} = \alpha^4 \frac{2}{3\pi} (Z\lambdabar)^2 \frac{1-v}{v} \left[\phi_e + \left(\frac{m_e}{m_\mu}\right)^2 \phi_\mu \right] \tag{1}$$

where

$$\nu = \frac{E^+ + E^-}{E} \quad \text{and} \quad \rho = \frac{E^+ - E^-}{E^+ + E^-}$$

and

α	1/137, fine structure constant;
$\lambdabar$	3.8616×10^{-11} cm, electron Compton wavelength;
v	k/E fraction of energy transferred to the pair;
T	$E - M$ kinetic energy of the muon.
$E^\pm$	the energy of the $e^\pm$.

The explicit form of the terms ϕ_e and ϕ_μ can be found in [99]. The kinematic ranges of ν and ρ are:

$$\frac{4m_e}{E} = \nu_{min} \leq \nu \leq \nu_{max} = 1 - 0.75\sqrt{e}\frac{m_\mu}{E}Z^{1/3}$$

$$0 = \rho_{min} \leq |\rho(\nu)| \leq \rho_{max}(\nu) = \left[1 - \frac{6m_\mu^2}{E^2(1-\nu)}\right]\sqrt{1 - \frac{4m_e}{\nu E}} \tag{2}$$

where $e = 2.718\ldots$.

E_c (PPCUTM in the program) is the energy cut-off; below this energy e^+e^--pair are treated as continuous energy loss, and above they are explicitly generated and $v_c = E_c/E$. The mean value of the energy lost by the incident muon due to e^+e^--pair with energy below E_c is:

$$E_{loss}^{pair}(Z, T, E_c) = 2E \int_{\nu_{min}}^{\nu_c} d\nu\, \nu \int_0^{\rho_{max}(\nu)} d\rho\, \frac{\partial^2 \sigma}{\partial \nu\, \partial \rho} \qquad \text{GeV barn/atom} \tag{3}$$

whereas the total cross-section for the emission of a hard e^+e^--pair is:

$$\sigma(Z, T, E_c) = 2 \int_{\nu_c}^{\nu_{max}} d\nu \int_0^{\rho_{max}(\nu)} d\rho\, \frac{\partial^2 \sigma}{\partial \nu\, \partial \rho} \qquad \text{barn/atom} \tag{4}$$

2.1 Parameterisation of energy loss and total cross-section

Instead of using the explicit formula (3) and (4), we have chosen to parameterise directly $E_{loss}^{pair}(Z, T, E_c)$ and $\sigma(Z, T, E_c)$ as:

$$\sigma(Z, T, E_c) = Z[Z + \xi_\sigma(1 + \gamma \ln Z)]\left[\ln \frac{E_{max}}{E}\right]^\alpha F_\sigma(Z, X, Y) \tag{5}$$

$$E_{loss}^{pair}(Z, T, E_c) = Z[Z + \xi_l(1 + \delta \ln Z)]E\left[\frac{E_c - E_c^{min}}{E}\right]^\beta F_l(Z, X, Y) \tag{6}$$

where $\xi_{\sigma,l}$, α, β, γ and δ are parameters obtained by a fitting procedure and $E_c^{min} = E\,\nu_{min} = 4m_e$ and $E_{max} = E\,\nu_{max}$

The functions F_i (Z,X,Y) ($i = \sigma,\, l$) have the form:

$$F_i(Z, X, Y) = F_{i0}(X, Y) + ZF_{i1}(X, Y) \tag{7}$$

where $F_{ij}(X, Y)$ denotes a function constructed from two polynomials

$$F_{ij}(X,Y) = \begin{cases} P_{ij}^{neg}(X,Y) & \text{if } Y \leq 0 \\ P_{ij}^{pos}(X,Y) & \text{if } Y > 0 \end{cases} \tag{8}$$

and P_{ij}^{neg}, P_{ij}^{pos} fulfil the conditions:

$$P_{ij}^{neg}(X,Y)_{Y=0} = P_{ij}^{pos}(X,Y)_{Y=0} \qquad \left. \frac{\partial P_{ij}^{neg}}{\partial Y} \right|_{Y=0} = \left. \frac{\partial P_{ij}^{pos}}{\partial Y} \right|_{Y=0}$$

The detailed form of the P_{ij} polynomials is:

$$
\begin{aligned}
P_{i0}^{neg}(X,Y) &= (C_1 + C_2 X + \cdots + C_6 X^5) + (C_7 + C_8 X + \cdots + C_{12} X^5)Y \\
&+ (C_{13} + C_{14} X + \cdots + C_{18} X^5)Y^2 + \cdots + (C_{31} + \cdots + C_{36} X^5)Y^5 \\
P_{i0}^{pos}(X,Y) &= (C_1 + C_2 X + \cdots + C_6 X^5) + (C_7 + C_8 X + \cdots + C_{12} X^5)Y \\
&+ (C_{37} + C_{38} X + \cdots + C_{42} X^5)Y^2 + \cdots + (C_{55} + \cdots + C_{60} X^5)Y^5 \\
P_{i1}^{neg}(X,Y) &= (C_{61} + C_{62} X + \cdots + C_{65} X^4) + (C_{66} + C_{67} X + \cdots + C_{70} X^4)Y \\
&+ (C_{71} + C_{72} X + \cdots + C_{75} X^4)Y^2 + \cdots + (C_{81} + \cdots + C_{85} X^4)Y^4 \\
P_{i1}^{pos}(X,Y) &= (C_{61} + C_{62} X + \cdots + C_{65} X^4) + (C_{66} + C_{67} X + \cdots + C_{70} X^4)Y \\
&+ (C_{86} + C_{87} X + \cdots + C_{90} X^4)Y^2 + \cdots + (C_{96} + \cdots + C_{100} X^4)Y^4
\end{aligned}
\tag{9}
$$

with

$$X = \ln \frac{E}{m_\mu} \qquad Y = \ln \frac{E_c}{v_j E} \qquad j = \sigma, l$$

where $v_{\sigma,l}$ are additional parameters of the fit. By a numerical (twofold) integration of the formulae (5) and (6) above, we have calculated 1800 *data points* in the range $Z = 1, 6, 13, 26, 50, 82, 92$ and the energy ranges $1\text{GeV} \leq T \leq 10$ TeV and $4m \leq E_c \leq T$ and performed a least-squares fit to determine the parameters. The fitted values of the parameters are in the DATA statements in the functions GPRSGM and GPRELM, which compute the formulae (5) and (6) respectively. The accuracy of the fit is:

$$
\frac{\Delta\sigma}{\sigma} \quad \leq \begin{cases} 10\% & \text{if } T \leq 5 \quad \text{GeV} \\ 5\% & \text{if } T > 5 \quad \text{GeV} \end{cases}
$$

$$
\frac{\Delta E_{loss}^{pair}}{E_{loss}^{pair}} \quad \leq \begin{cases} 10\% & \text{if } T \leq 5 \quad \text{GeV} \\ 4\% & \text{if } T > 5 \quad \text{GeV} \end{cases}
$$

The function GPRELM contains a second formula to calculate the total energy lost by the muon due to direct e^+e^--production used when $E_c \geq E_{\max} = E - 0.75\sqrt{e}m_\mu Z^{1/3}$. This formula describes the total energy loss with an error less than 1%:

$$
\begin{aligned}
E_{loss}^{pair}(Z,T) &= E_{loss}^{pair}(Z,T,E_c = E_{max}) \tag{10} \\
&= Z(Z+1)E_{max}[d_1 + (d_2 X + d_3 Y) + (d_4 X^2 + d_5 XY + d_6 Y^2) + \\
&+ \cdots + (d_{22} X^6 + d_{23} X^5 Y + \cdots + d_{28} Y^6)]
\end{aligned}
$$

where $X = \ln(E/m_\mu)$ and $Y = Z^{1/3}$. The fitted parameters d_i can be found in the DATA statement in the function GPRELM.

Simulation of e^+e^- -pair production by muons

1   Subroutines

CALL **GPAIRM**

GPAIRM generates the e^+e^- -pair radiated by a high energetic muon. It uses the following input and output:

input: via common block /GCTRAK/
output: via common block /GCKING/

GPAIRM is called automatically from the tracking routine GTMUON if, and when, the parent muon reaches its radiation point during the tracking.

2   Method

The double differential cross-section for the process can be written [99]:

$$\frac{d^2\sigma}{d\nu\,d\rho} \;=\; \alpha^4\frac{2}{3\pi}(Z\lambda)^2\cdot\frac{1-\nu}{\nu}\left[\phi_e + (m/M)^2\,\phi_\mu\right] \tag{1}$$

All the quantities in the expression above are defined in [PHYS450]. By computing this cross-section for different (ν,ρ) points, it can be seen that:

1. the **shape** of the functions $\frac{d^2\sigma}{d\nu\,d\rho}$ and $\frac{d\sigma}{d\nu}\int d\rho\frac{d^2\sigma}{d\nu\,d\rho}$ practically does not depend on Z

2. the dominant contribution comes from **the low ν region:**

$$\nu_{min} = \left(4m/E\right) \le \nu \le 100 * \nu_{min} \tag{2}$$

3. in this low region $(d^2\sigma/d\nu\,d\rho)$ **is flat** as a function of ρ

Therefore, we propose the following sampling method as a rough approximation:

1. In the low ν region the differential cross-section

$$\frac{d\sigma}{d\nu} = \int d\rho\frac{d^2\sigma\,K}{d\nu\,d\sigma}$$

can be approximated as:

$$\frac{d\sigma}{d\nu} \approx \left[1 - \frac{\nu_{min}}{\nu}\right]^{1/2}\frac{1}{\nu^a} \qquad \text{with:} \quad a = 2 - \frac{\ln E}{10} \qquad (E \text{ in GeV}) \tag{3}$$

We can write:

$$\frac{d\sigma}{d\nu} \approx f(\nu)g(\nu) \tag{4}$$

where,

$$f(\nu) = \frac{(a-1)}{\frac{1}{\nu_c^{a-1}} - \left(\frac{1}{\nu_{max}}\right)^{a-1}} \frac{1}{\nu^a} \tag{5}$$

is the normalised distribution in the interval $[\nu_c, \nu_{max}]$ and

$$g(\nu) = \left[1 - \frac{\nu_{min}}{\nu}\right]^{1/2} \tag{6}$$

is the rejection function.

2. r_1 and r_2 being two uniformly distributed random numbers in the interval $[0, 1]$:

    –   Sample ν from the distribution $f(\nu)$ as:

$$\nu = \left(\frac{1 - r_1}{\nu_c^{a-1}} \frac{r_1}{\nu_{max}^{a-1}}\right)^{\frac{1}{1-a}} \tag{7}$$

    –   Accept ν if $r_2 \leq g(\nu)$ (8)

3. Then compute

$$\rho_{max}(\nu) = \left[1 - \frac{6M^2}{E^2(1-\nu)}\right]\left[1 - \frac{4m}{\nu E}\right]^{1/2} \tag{9}$$

and generate ρ uniformly in the range $[-\rho_{max}, +\rho_{max}]$.

After the successful sampling of (ν, ρ), `GPAIRM` generates the polar angles of the radiated e^+e^--pair with respect to an axis defined along the parent muon's momentum. Θ is assigned the approximate average value:

$$\Theta = \frac{M}{E} \tag{10}$$

ϕ^+ is generated isotropically and $\phi^- = \phi^+ + \pi$

Muon-nucleus interactions

1   Subroutines

```
CALL GMUNUI
```

`GMUNUI` computes and stores in the appropriate bank the value of the muon-nucleus cross-section for a given material. It is called at initialisation time by `GPHYSI`.

```
CALL GMUNU
```

`GMUNU` is called by `GTMUON` every time a muon-nucleus interaction has to happen. It generates the final state particles as well as the outgoing muon. A call to `GUHADR` is performed if `IMUNU` (which is the variable set by the `MUNU` data record) is equal to 1. An inelastic interaction is forced (which could also be a fission in case of heavy materials). The secondaries from the π-nucleus interaction are always generated if `IMUNU` is equal to 1, irrespectively of the value of `IHADR`.

Note: `IMUNU` should be set to 1 only when using the `GHEISHA` hadronic interactions package. Setting it to 1 when using `FLUKA` can give unpredictable results.

```
VALUE = GMUSIG (E,E1,COSTET)
```

E   (REAL) initial μ energy;
E1   (REAL) final μ energy;
COSTET   (REAL) μ scattering angle.

This function returns the value of the differential cross-section in millibarns for a muon of energy `E` to generate a nuclear interaction recoil with energy `E1` at an angle the cosine of which is `COSTET`.

2   Method

This set of routines generates the interactions of muons with the nuclei of the tracking material. The code is a straight translation into the `GEANT` style of the corresponding code from the `GHEISHA` Monte Carlo Program. The `GHEISHA` routines `CASMU` and `CALIM` have been used [1].

The information contained in this chapter is mainly taken from the `GHEISHA` manual to which the user is referred. The muon-nucleus inelastic cross-section is taken as 0.0003 mb for a nucleon when the energy of the incoming muon is $E < 30$ GeV, and slowly increases for $E > 30$ GeV according to the law:

$$\sigma = 0.3 * (E/30)^{0.25} \quad [\mu b]$$

The energy and angle of final state muon is generated according to the "free quark parton model". If E is the energy of the incoming muon and Ω and W the angle and the energy of the outgoing muon, the differential cross-section can be written as:

$$\frac{d\sigma}{d\Omega dW} = \gamma(\sigma_T + \epsilon \sigma_S)$$

where:

$$\Gamma = \frac{k\alpha}{2\pi}\frac{W}{E}\frac{1}{1-\epsilon}$$

$$\epsilon = \left[1 + 2\frac{Q^2 + \nu^2}{Q^2}\tan^2\theta^2\right]$$

Q^2 and ν are the normal scaling variables expressed by:

$$Q^2 = -q^2 = 2(EW - |p||p'| \cos\theta - m_{-\mu}^2) \quad \text{and} \quad \nu = E - W$$

here σ_T and σ_S are the photo-absorption cross-sections for transverse and longitudinal photons respectively for which the relation used is:

$$\sigma_S = 0.3 \left(1 - \frac{1}{1.868} Q^2 \nu\right) \sigma_T$$

and σ_T is assumed to be constant $\sigma_T = 0.12$ mb. For the incident flux K of the photons Gillman's convention is used:

$$K = \nu + Q^2/2\nu$$

A three-dimensional importance sampling in the variables E, W and θ is performed each time an interaction has to occur.

This set of routines only works if `GUPHAD` calls `GPGHEI` and `GUHADR` calls `GHEISH`. The hadrons are generated in an approximate way. The virtual photon is replaced by a real pion of random charge with the same kinetic energy. Then the `GUHADR` routine is called to generate a π-nucleus inelastic scattering. While the final state generated this way gives a good approximation for calorimetric purposes, the kinematics of the final state may be a rather poor approximation of reality. The muon-nucleus interactions are activated by the `MUNU` data record of `GEANT`. After a muon-nucleus interaction the muon will still be the current particle. If `MUNU 1` has been specified, secondaries coming from the interaction of the virtual photon with the nucleus will be in the `GEANT` temporary stack. If `MUNU 2` has been specified, then the secondary particles will not be generated and the energy lost by the muon will be added to `DESTEP`. For each material a table of muon-nucleus cross-sections is stored at initialisation time. See material bank structure for details.

The GEANT/GHEISHA Interface

1   Introduction

There are two packages to describe the hadronic showers in matter which are available to the users of `GEANT`: `GHEISHA` [1] and `FLUKA` (see [`PHYS520`]).

The `GHEISHA` code generates hadronic interactions with the nuclei of the current tracking medium, evaluating cross-sections and sampling the final state multiplicity and kinematics, while the `GEANT` philosophy is preserved for the tracking. The `GHEISHA` code is stored in the `GEANH` car file.

The `GHEISHA` printing flags can be set via the `GEANT SWIT` data record: each switch greater than 100 but smaller that 111 sets the corresponding printing flag of `GHEISHA` modulo 100, so that `SWIT 105` will set the printing flag 5 of `GHEISHA`. Setting the printing flags of `GHEISHA` the following information will be displayed:

`NPRT(1)`   one header for each track in the shower;
`NPRT(2)`   all tracking information;
`NPRT(3)`   kinematic of decays (not effective);
`NPRT(4)`   kinematic of nuclear interactions;
`NPRT(5)`   kinematic of electromagnetic interactions (not effective);
`NPRT(6)`   material constants, dE/dX and absorbed energies (not effective);
`NPRT(7)`   event summary;
`NPRT(8)`   history of all interactions/decays;
`NPRT(9)`   free;
`NPRT(10)`   tables of the geometry, cross-sections, etc.;

`NPRT(1)`, `NPRT(2)` and `NPRT(6)` should be used only in case of suspected errors. `NPRT(8)` produces the most illustrative output. Those flags work in conjunction with the `DEBUG` data record of `GEANT`.

1.1   Description of the routines

```
   CALL GHESIG   (P,EK,AVER,A,Z,W,NLM,DENS,CORR,IPART)
```

`P`   (`REAL`) momentum of the particle (in GeV/c);
`EK`   (`REAL`) kinetic energy of the particle (in GeV);
`AVER`   (`REAL`) average mass number of the material;
`A(NLM)`   (`REAL`) vector containing the mass numbers of the components of the mixture, the same as `AVER` in case of an element;
`Z(NLM)`   (`REAL`) vector containing the atomic numbers of the components of the mixture, or the atomic number in case of an element;
`W(NLM)`   (`REAL`) vector of length NLM containing the relative weights of the components of the mixture (normalised to one), one in case of an element;
`NLM`   (`INTEGER`) number of components of the mixture, 1 in case of an element;
`DENS`   (`REAL`) density of the material;
`CORR`   (`REAL`) if this parameters is > 0, then corrections are applied to the cross-section; should be used in case of inorganic scintillators;
`IPART`   (`INTEGER`) `GEANT` particle code.

This routine returns the total macroscopic cross-section in cm^{-1}. The correction flag is taken from the 26th word of the *next* bank in the tracking medium linear structure pointed at by `LQ(JTMED-NUMED)`.

The cross-sections on nucleus are known only for pions and protons. The general law:

$$\sigma(A) = 1.25 * \sigma_{tot}^{Proton} \; A^{\alpha}$$

is used but it is valid only for momenta > 2 GeV. The parametrisation done gives only a behaviour averaged over momenta and particle types. For H, Al, Cu and Pb the measured cross-sections are stored in `DATA` statements.

The stored cross-sections are the pre-calculated `GHEISHA` ones. As a starting point the measured cross-sections of pions, kaons, protons, antiprotons and neutrons on protons are used. The cross-sections tabulated are measured values taken from the CERN HERA compilations. The values for K_s^0/K_l^0 are updated as of July 1980. Strange baryon cross-section are calculated using a parametrisation in terms of quark-quark forward scattering amplitudes and optical theorem. The additive quark quark scattering model is used. All the cross-sections are contained in data statements so no external file is needed for `GHEISHA`.

CALL **GPGHEI**

This routine returns the distance to the next hadronic interaction according to the `GHEISHA` cross-sections. It calls `GHESIG` and is called by `GUPHAD`. The default copy provided in the `GEANT` library uses the `GHEISHA` shower code:

```
      SUBROUTINE GUPHAD
*
*******************************************************************
*                                                                 *
*    GEANT   user routine called at each step to evaluate         *
*    the remaining distance to the hadronic interaction point     *
*                                                                 *
*******************************************************************
*
      CALL GPGHEI
*
      END

      SUBROUTINE GUHADR
*.
*******************************************************************
*                                                                 *
*      GEANT  user routine called when a hadronic process         *
*      has been selected in the current step, in order to         *
*      generate the final particle's state                        *
*                                                                 *
*******************************************************************
*
      CALL GHEISH
*
      END
```

CALL **GHEISH**

This is the main steering routine for the hadronic interactions and is a fan-out to the various *cascade* routines of `GHEISHA` which treat the particular hadronic interaction. Here the kind of interaction is stored in the `INT` flag, with the following meaning:

```
INT=0      no interaction (NONE);
INT=1      elastic scattering occurs (ECOH);
INT=2      inelastic incoherent interaction occurs (INHE), 1 and 2 include also nuclear reaction processes
           at very low energies;
INT=3      nuclear fission with inelastic scattering occurs (FISS);
INT=4      neutron nuclear capture occurs (CAPT).
```

After the interaction has been selected, the appropriate cascade routine is called. Upon exit from this there is a check whether the interaction has generated new particles or not. If yes, the new particles are copied in the GEANT temporary stack (GKING). If the particle is a heavy fragment or a proton and it is below the energy cut specified via the CUTS data record, it is not stored in the stack but the kinetic energy is collected. The size of the GHEISHA stack is parametrised, and its limit is currently set to 100 in sequence GCKMAX. The user is left to decide in GUSTEP what to do with the new tracks. This routine is called also in case of a stopping hadron, i.e. with kinetic energy below the GEANT cuts. In this case the routine GHSTOP (see later) is called to handle the stopping hadron. The printing flags for GHEISHA are also set in this routine according to the current value of IDEBUG.

This routine must be called by the user routine GUHADR (see above).

As explained above, for inorganic scintillators such as the BGO, it is possible to activate a correction to the hadronic cross-section. This is done via the routine GSTPAR in the following way:

```
      CALL GSTPAR(ITMED,'GHCOR1',1.0)
```

The parameter is actually a flag which, if different from 0, triggers the calculation of the cross-section correction, but in view of future developments it is good practice set it to 1.0 when those corrections are required. ITMED is the tracking medium number as used in GSTMED for which corrections are requested. This routine has to be called before GPHYSI.

CALL **GHSTOP**

This is an internal routine used to handle stopping particles, called by GHEISH. Here again we have a switch to the various routines handling stopping particles. In particular this routine can lead to nuclear absorption for negative pions and negative kaons (ABSO) and to annihilation for antineutrons, and antiprotons (ANNH). The kinetic energy is completely absorbed, and in the case of an unstable particle, the particle is decayed at rest via the standard GEANT decay routine GDECAY.

The `GEANT/FLUKA` Interface

1   Subroutines

> CALL **FLINIT**

`FLINIT` initialises the `FLUKA` variables and reads data from a file (flukaaf.dat) which is automatically opened. `FLINIT` is called from `FLDIST` when a hadron enters there first time in the run.

> CALL **FLDIST**

`FLDIST` computes the distance to the next interaction point. It calls the `FLUKA` routines to compute the cross-sections for all particles except neutrons with kinetic energy below 20 MeV for which `GHEISHA` routines are called. `FLDIST` is called from the user routine `GUPHAD` where the hadronic package can be chosen.

> CALL **FLUFIN**

`FLUFIN` calls the `FLUKA` routines to generate the hadronic interaction. It passes the particle to `FLUKA` interaction routines and puts the eventual secondary particles to the `GEANT` stack. `FLUFIN` is called from the user routine `GUHADR`.

2   Method

`FLUKA` [2, 3, 4, 5, 6, 101, 102] is a simulation program which as a standalone code contains transport and the physical processes for hadrons and leptons and tools for geometrical description. In `GEANT`, only the hadronic interaction part is included.

The total cross-section of the hadronic processes is computed by `FLUKA` routines called from `FLDIST` (the cross-section for neutrons below 20 MeV is computed in `GHEISHA`). If hadronic intercation is chosen in `GEANT` tracking routine, the particle is passed to `FLUFIN`.

If particles are stopping (i.e. their energy is below the cut-off energy), their kinetic energy is deposited. However, if the particle can decay (π^+, $K^\pm$) it is forced to decay, or if it is an annihilating particle (π^-, $\bar{n}$, $\bar{p}$), it is sent to `FLUKA` routines for annihilation. The neutrons with kinetic energy below 20 MeV are passed to `GHEISHA`.

If the particle is not stopping, a sampling is done between elastic and inelastic processes. The cross-sections have been computed in `FLDIST` in the same time as the total cross-section. The particle is sent correspondingly to the elastic or inelastic interaction routines. After the interaction, the eventual secondary particles are written to `GEANT` stack. The program flow is shown in figures 46 and 45.

When the tracking media is a mixture or a compound material (defined by `GSMIXT`, see [`CONS110`]), the atom with which the interaction is taking place is chosen by sampling on the basis of the cross-sections. This is important especially in hydrogenous materials.
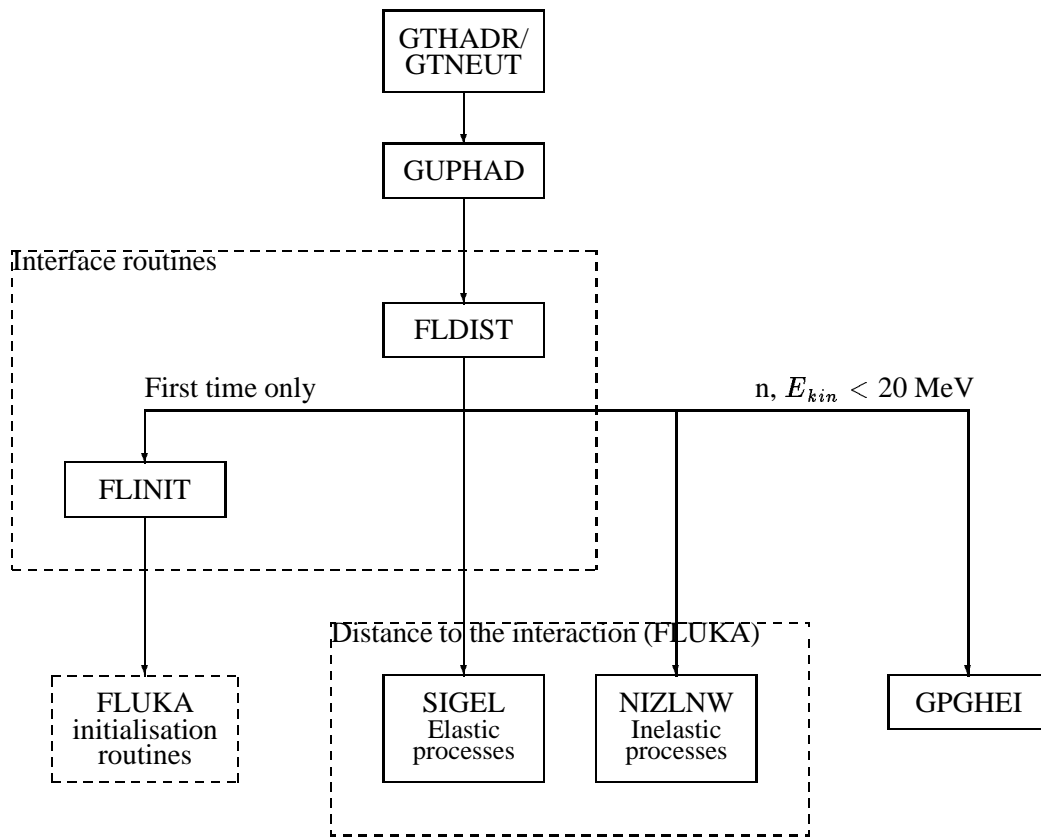

Figure 45: Program flow for calculation of the distance to the next interaction point
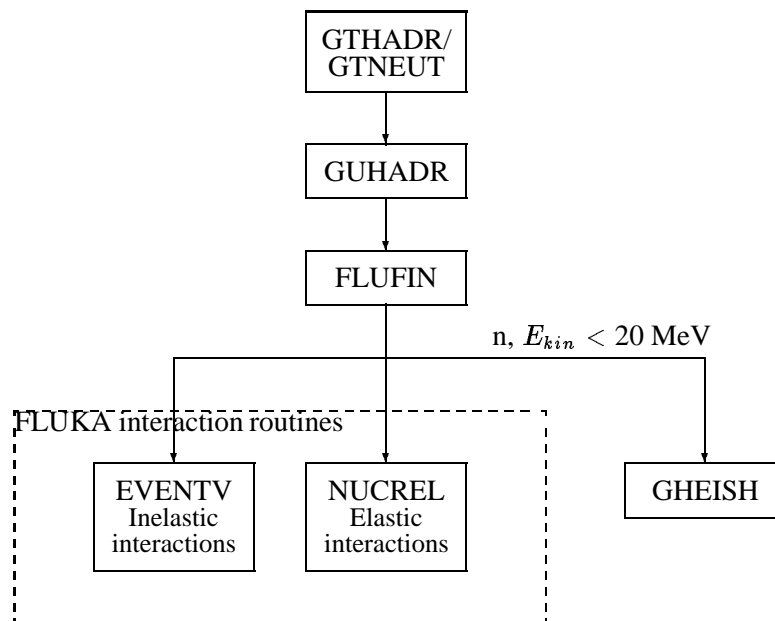

Figure 46: Program flow for generating secondary particles

The `GEANT/MICAP` interface

1   Subroutines

CALL **GMORIN**

`GMORIN` initialises the `MICAP` variables and reads the cross-section file for the materials that have been defined. It is called from `GFMDIS` when a neutron with kinetic energy below 20 MeV enters there first time.

CALL **GFMDIS**

`GFMDIS` computes the distance to the next interaction points. It calls the `FLUKA` routines to compute the cross-sections for all particles except neutrons with kinetic energy below 20 MeV for which `MICAP` function `SIGMOR` is called. `GFMDIS` is called from the user routine `GUPHAD` where the hadronic package can be chosen. The only difference between `GFLDIS` (see [PHYS520]) and `GFMDIS` is that for the former, `GHEISHA` hadronic package is called for the neutrons below 20 MeV, and for the latter, the low-energy neutrons are handled by `MICAP`.

CALL **GFMFIN**

`GFMFIN` calls the `FLUKA` routines to generate the hadronic interaction. For the neutrons with kinetic energy below 20 MeV `GMICAP` is called. The only difference between `GFLFIN` (see [PHYS520]) and `GFMFIN` is that for the former, `GHEISHA` hadronic package is called for the neutrons below 20 MeV, and for the latter, the low-energy neutrons are handled by `MICAP`. `GFMFIN` is called from the user routine `GUHADR`.

CALL **GMICAP**

`GMICAP` calls the `MICAP` routines to handle the low-energy interaction of neutrons. It writes the eventual secondaries to the `GEANT` stack. `GMICAP` is called from `GFMFIN`.

2   Method

`MICAP` (A Monte Carlo Ionization Chamber Analysis Package) [103], [104] is a Monte Carlo system to analyze ionisation chamber responses. As a standalone program it contains the code for formatting the cross-section files, neutron and photon transport, the geometry definitions and the code for the chamber response. In `GEANT`, only the sampling of the neutron interactions from the already prepared cross-section file is included. The interface between `GEANT` and `MICAP` has been extracted from `GCALOR` package [105] by C.Zeitnitz and T. Gabriel.

When using `GEANT-MICAP` interface the low-energy neutrons are handled in `MICAP` routines. Other hadrons and high-energy neutrons are passed to `FLUKA` interaction routines. For low-energy neutrons, the total cross-section is given by `MICAP` and if the neutron interaction is chosen by `GEANT` tracking routine, `GMICAP` reads the cross-section for neutron interactions processes, samples and generates the interaction and the returns the secondary particles (nucleons, heavy fragments, or photons) to `GEANT`. Information on the recoil nucleus (atomic number `AMED`, charge `ZMED` and kinetic energy `ERMED`) can be found in `MCRECO` common block. The program flow is shown in figures 48 and 47.

`MICAP` uses pointwise cross-section data (as a difference to so called group cross-sections where the data are averaged over certain energy intervals). This method has the advantage that the resonances are not smoothed by averaging the data. The neutron cross-section are available for the following isotopes:
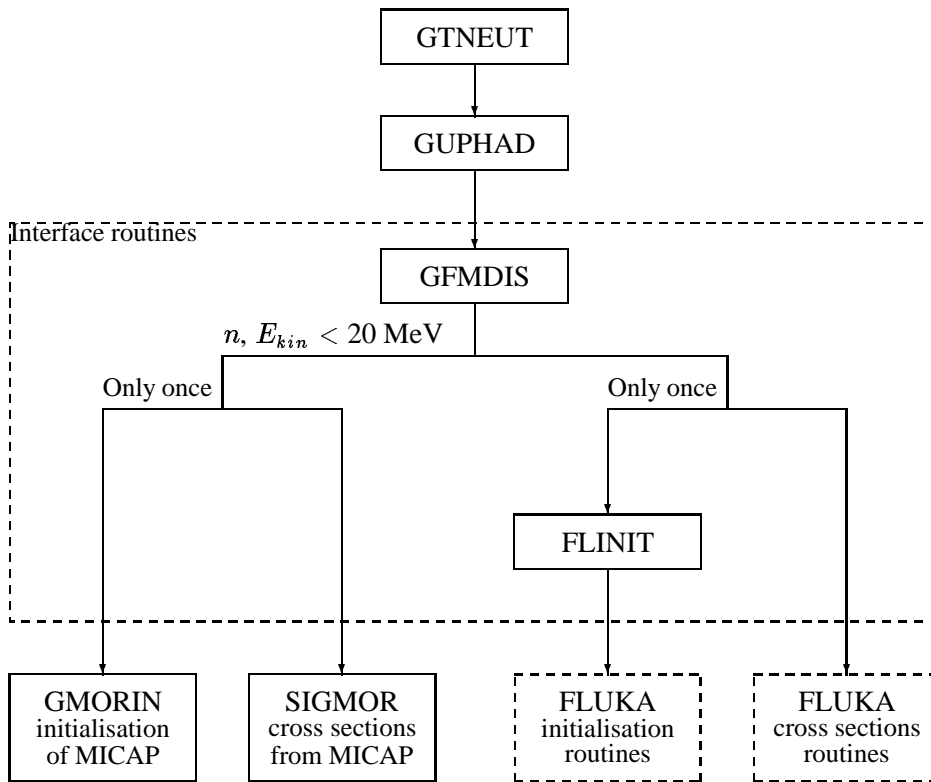

Figure 47: Program flow for calculation of the distance to the next interaction point
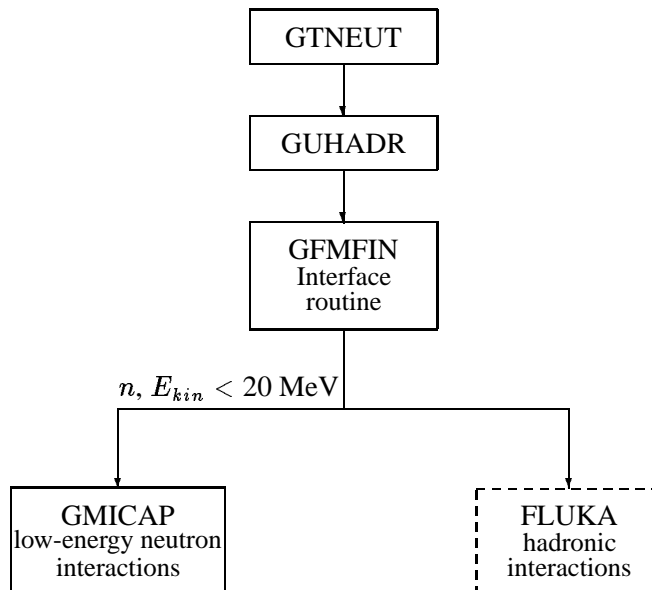

Figure 48: Program flow for generating secondary particles

Hydrogen (bound)	Argon
Hydrogen (free)	Calcium
Lithium (6,7)	Chromium
Boron (10,11)	Iron
Carbon	Nickel
Nitrogen	Copper
Oxygen	Molybdenum
Fluorine	Copper
Sodium	Molybdenum
Magnesium	Barium
Aluminum	Tantalum
Silicon	Lead
Chlorine	Uranium (235,238)

If the cross-sections are not found for some of the defined materials, a warning is printed first at the initialisation time telling which cross-section are used (the closest Z available) instead. Then, an additional warning is printed each tracking step.

The tracking package

1 Introduction

In GEANT *tracking* a particle through a geometry of objects consists in calculating a set of points in a seven-dimensional space (x, y, z, t, p_x, p_y, p_z) which is called the trajectory of the particle. This is achieved by integrating the equations of motion over successive *steps* from one trajectory point to the next and applying corrections to account for the presence of matter.

To have a detailed description of the kinematic of the particle it would be necessary to calculate a trajectory point every time the component of the momentum change. This is not possible because it would mean calculating an enormously large number of points. Processes like the deviation of a charged particle in a magnetic field, the loss of energy due to bremsstrahlung and ionisation or the deviation due to elastic electromagnetic scatterings are essentially continuous. An arbitrary distinction is thus made between discrete and continuous processes, controlled by a set of thresholds which can be set by the user. A particle trajectory is thus a set of points at which a discrete process has happened.

The tracking package contains a subprogram which performs the tracking for all particles in the current event and for the secondary products which they generate, plus some tools for storing the space point coordinates computed along the corresponding trajectories.

2 The step size

When tracking particles through a complex structure one of the critical tasks is the estimation *a priori* of the step size. This is performed automatically by the program. For a particle with a given energy the step size depends primarily on the intrinsic properties of the particle (mass, charge, lifetime, etc.) and on the characteristics of the current medium. The dependence may be due either to the (quasi)continuous processes which usually impose a limit to the interval of integration (energy loss, multiple scattering ...) or to the occurrence of a discrete process which introduces a discontinuity in the trajectory (decay, electromagnetic or hadronic interaction). The modification of the kinematic parameters (position and energy) due to continuous processes between two discrete ones is taken into account and the necessary modifications are applied at the end of the step.

In addition to the physical effects there are constraints of a geometrical nature, the step being limited by the path length to the medium boundary. In practice, the step size depends ultimately on a set of tolerances and cuts, which the program will set automatically, but which may be also optimised by the user, such as:

- the maximum turning angle due to magnetic field permitted in one step;

- the maximum fractional energy loss in one step;

- the maximum geometrical step allowed;

- the accuracy for crossing medium boundaries;

- the minimum step size due to either energy loss or multiple scattering.

These quantities are part of the so-called tracking medium parameters. They can either be calculated by the program or provided by the user and are stored in the data structure JTMED, through the routine GSTMED (see

[CONS]). Usually, this is done together with the initialisation of the geometrical setup. The optimisation is by no means trivial as the economy of computing time should not lead to an unacceptable loss of accuracy.

Other information required for the computation of the step size is found in the data structures JPART and JMATE, for the properties of the particles and of the materials, and in the data structure JVOLUM, for the current medium and its geometrical boundaries. The communication between the tracking package and the structure JVOLUM is achieved through the basic subroutines of the geometry package GMEDIA, GTMEDI, GTNEXT and GINVOL (see [GEOM]). Some information is computed at tracking time such as the probability of occurrence of an interaction.

For convenience every particle is assigned a tracking type:

1. γ (GTGAMA);

2. $e^{\pm}$ (GTELEC);

3. neutral hadrons and neutrinos (GTNEUT);

4. charged hadrons (GTHADR);

5. muons (GTMUON);

6. geantinos, particles only sensitive to geometry used for debugging (GTNINO);

7. Čerenkov photons (GTCKOV);

8. heavy ions (GTHION).

Which processes have to be considered for a given particle depends on its tracking type. For the hadrons it depends also, through the subroutine GUPHAD, on which hadronic processes from GHEISHA, FLUKA have been selected (see [PHYS001]).

3   Transport subroutines

At the event level the tracking is controlled by the subroutine GTREVE called by the subroutine GUTREV where the user can perform additional actions. GTREVE loops over all vertices and for every vertex in turn stores all tracks in the stack JSTAK. Then tracking begins: particles are fetched from JSTAK by GLTRAC which prepares the commons for tracking. GUTRAK is then called, which calls GTRACK. The subroutine GTRACK transports the particle up to the its end: stop, decay, interaction or escape. During this phase it may happen that secondary products have been generated and stored by the user, as explained below, in the JSTAK stack, and possibly in the permanent structure JKINE.

The subroutine GTRACK transports the track through the geometrical volumes identifying, through the subroutine GTMEDI, every new volume which the particle has reached, and storing the corresponding material and tracking medium constants in the common blocks /GCMATE/ and /GCTMED/. The actual transport is performed by a different routine for each tracking type, as indicated in the previous section. These compute the physical step size according to the activated physics processes, and compute the geometrical limit for the step, only when necessary, through GTNEXT, and propagate the particle over the computed step.

4   Magnetic field transport routines

Once the step size has been decided, transport proceeds along a straight lines for all neutral particles and for charged particle in absence of magnetic field. When magnetic field is present, the direction of charged particles will change along the step. The routine GUSWIM calculates the deviation in magnetic field over a given step. Depending on the tracking medium parameter IFIELD the GUSWIM routine calls:

- GRKUTA for inhomogeneous fields, IFIELD=1;

- GHELIX for quasi-homogeneous fields, IFIELD=2;

- GHELX3 for uniform fields along the z axis, IFIELD=3).

GRKUTA and GHELIX call the user subroutine GUFLD to obtain the components of the field in a given point. GHELX3 takes the value of the field from the tracking medium parameter FIELDM.

5 The subroutine GUSTEP

The current track parameters are available in the common /GCTRAK/ together with all variables necessary to the tracking routines for the control of the step size. In addition, a few flags and variables are stored in the common block /GCTRAK/ to record the history of the current step:

- The flag INWVOL informs on the boundary crossing:

    0   transport inside a volume;
    1   entering a new volume or beginning of new track;
    2   exiting a volume;
    3   exiting the first mother;

- The flag ISTOP informs on the particle status:

    0   normal transport;
    1   particle has disappeared (decay, interaction...);
    2   particle has crossed a threshold (time, energy...).

- The array LMEC informs on the *mechanisms* active in the current step. The mechanism names are stored in ASCII equivalent in LMEC(1...NMEC).

- The total energy loss in the current step is stored in the variable DESTEP.

This information is necessary for the user to take the proper actions in the subroutine GUSTEP which is called by GTRACK at the end of every step and when entering a new volume.

The variable NGKINE in common /GCKING/ contains the number of secondary particles generated at every step, and which are stored in the same common. Depending on the application and on the particle type the user may then take the appropriate action in GUSTEP:

- ignore the particle;

- store the secondary produced in the JSTAK stack for further tracking;

- store the secondary also in the JKINE/JVERTX structure where it will be kept till the end of the event.

6 Connection with the detector response package

The detector response package ([HITS]) allows to establish a correspondence between the volumes seen by the particle and the active components of the detectors. When entering a new volume in GTRACK the subroutine GFINDS is called. If the volume has been declared by the user as a sensitive detector through appropriate calls to GSDET and if the corresponding tracking medium constant ISVOL is non zero, GFINDS fills the common block /GCSETS/ with the information to identify uniquely the detector component. This enables the user, in GUSTEP, to record the hits in the proper JHITS substructure [HITS].

7 Connection with the drawing package

The coordinates of the space points generated during the tracking are available at each step in the common block/GCTRAK/. In GUSTEP the user can store them in the structure JXYZ with the help of the subroutine GSXYZ. This information can be used later for debugging (subroutine GPJXYZ) or for the graphical representation of the particle trajectories [DRAW].

Storing secondary tracks in the stack

```
    CALL GSKING  (IT)
```

IT   (`INTEGER`) number of the track to be stored for subsequent tracking, if `IT=0` all secondary tracks generated in the current step are stored for tracking.

During transport, particles can generate new particles, called secondary. In `GEANT` these particles are stored in the common `/GCKING/` (see [`ZZZZ010`] for an explanation of the variables in this common). The number of particles generated in the current step is `NGKINE` (common `/GCKING/`). If no user action is taken, the variable `NGKINE` is reset to 0 at the beginning of the subsequent step and these particles are not transported.

To be transported by `GEANT`, these particles need to be stored in the data structure `JSTAK` (see [`TRACK399`]) which normally is a LIFO stack: the last particle generated is the first one to be tracked when the current one stops. The order of tracking can be changed by the user, plase see [`TRAK310`] for more information on this subject.

The routine `GSKING` moves particles from the `/GCKING/` common to the `JSTAK` structure, where `GEANT` looks for particles to transport.

When a particle is fetched from the `JSTAK` data structure, its place is freed for a new one, so the information on the initial kinematics of this track is lost. It may be useful in some occasion to record the initial kinematic of a track and save it till the end of the event. This is accomplished by storing the particle information both in the `JSTAK` data structure and in the `JVERTX`/`JKINE` one, which is permanent throughout the life of the event. As already said in [`KINE100`], this should not be done by the user calling directly the `GSVERT`/`GSKINE` routines during tracking, but rather controlling the action of `GSKING` via the array `IFLGK` in common `/GCKING/`. If the particle number `IG` generated in the current step ($1 \leq$ `IG` $\leq$ `NGKINE`) is being moved to the `JSTAK` *stack*, either singularly or together with all the other particles generated in the current step (setting the argument of `GSKING` to 0), the action performed depends on `IFLGK(IG)`:

`IFLGK(IG)`<0 the particle is ignored;
          $=0$ the particle is stored on the temporary stack `JSTAK` to be transported;
          $=1$ the particle is stored on the temporary stack `JSTAK` to be transported *and* in the `JKINE` data structure attaching it to a vertex created in the current position (array `VECT(I)`, `I=1,3` in the `/GCTRAK/` common);
          >1 the particle is stored on the temporary stack `JSTAK` to be transported *and* in the `JKINE` data structure attaching it to vertex number `IFLGK(IG)`, which must exist.

If `IFLGK(IG)`>0, after the call to `GSKING`, `IFLGK(IG)` is set to the newly created track number in `JKINE`. The number of the vertex used is returned in `IFLGK(NGKINE+1)`. This feature allows the user to identify the created vertex and tracks via the routines `GSVERU` and `GSKINU` (see [`KINE100`]).

Example

In case of a hadronic interaction, discard the neutrinos, store the protons in the permanent data structure `JVERTX`/`JKINE`, and store all the other particles produced in the temporary stack.

Add to the protons in the `JKINE` bank the `JVOLUM` and copy number of the volume and the number of the tracking medium where they have been produced by an interaction.

```
      SUBROUTINE GUSTEP
+SEQ,GCKING,GCVOLU,GCTMED.
      CHARACTER*4 CHCASE
      DIMENSION UBUF(3)
      .
      .
      .
      CALL UHTOC(KCASE,4,CHCASE,4)
      IF(CHCASE.EQ.'HADR') THEN
         DO 10 IG=1, NGKINE
            IPART = GKIN(5,IG)
            IF(IPART.EQ.4) THEN
*---              Discard neutrinos
               IFLGK(IG)=-1
            ELSEIF(IPART.EQ.14) THEN
*---              Save protons in JKINE and transport them
               IFLGK(IG)=1
            ELSE
*---              Simply transport the rest
               IFLGK(IG)=0
            ENDIF
  10     CONTINUE
      ENDIF
*---              Perform action on all the particles
      CALL GSKING(0)
*---              Add information to the JKINE bank
      DO 20 IG=1,NGKINE
         IPART = GKIN(5,IG)
         IF(IPART.EQ.14) THEN
*---              This is a proton
*---              Get the track number
            IT = IFLGK(IG)
            NUBUF = 3
            UBUF(1) = LVOLUM(NLEVEL)
            UBUF(2) = NUMBER(NLEVEL)
            UBUF(3) = NUMED
            IADR = 0
*---              Store the information
            CALL GSKINU(IT,NUBUF,UBUF,IADR)
         ENDIF
  20  CONTINUE
```

Altering the order of traking secondary particles

When secondary particles are produced during particle transport, if the user wants to transport them in turn, they must be stored by a call to GSKING or GSKPHO onto the temporary stack JSTAK. As explained in [TRAK310], this is a LIFO structure, where the last particle introduced is the first to be extracted to be transported. It may be sometimes interesting to alter the order of tracking, for instance to decide whether the current event is worth completing or whether it should be skipped to go to next one.

It is possible in GEANT to alter the behaviour of the JSTAK structure using one of the words of the stack, normally reserved for the user. Stack ordering is activated via the data record SORD 1. This will set to 1 the variable ISTORD in common /GCSTAK/, which is by default initialised to 0.

When stack ordering is activated, the routine GLTRAC, which fetches the next particle to be tracked from JSTAK, instead of the last one, will select the one with the maximum value of the user word. This user word must be set by the user in the variable UPWGHT in the common /GCTRAK/ prior to the call to GSKING to store each secondary.

If, for instance, all the protons must be tracked first, in order of production, and all the other particles after, again according to their time of production, the following code should appear in GUSTEP:

```
      SUBROUTINE GUSTEP
+SEQ,GCTRAK,GCKING
         .
         .
         .
      DO 10 IG=1,NGKINE
*---        Younger particles tracked first
*---        Add to the current time of flight the time delay of
*---        the secondary
         UPWGHT = -TOFG-TOFD(IG)
         IPART = GKIN(5,IG)
         IF(IPART.EQ.14) THEN
*---        This is a proton, add a 100 microseconds to have it
*---        tracked first
            UPWGHT = UPWGHT+1E-4
         ENDIF
*---        Now store the particle in the GEANT stack
         CALL GSKING(IG)
  10  CONTINUE
```

Users should be aware of the fact that ordering the stack will change the results, because transport depends on random numbers which will be different for the same particle in the two cases.

The temporary stack data structure `JSTAK`
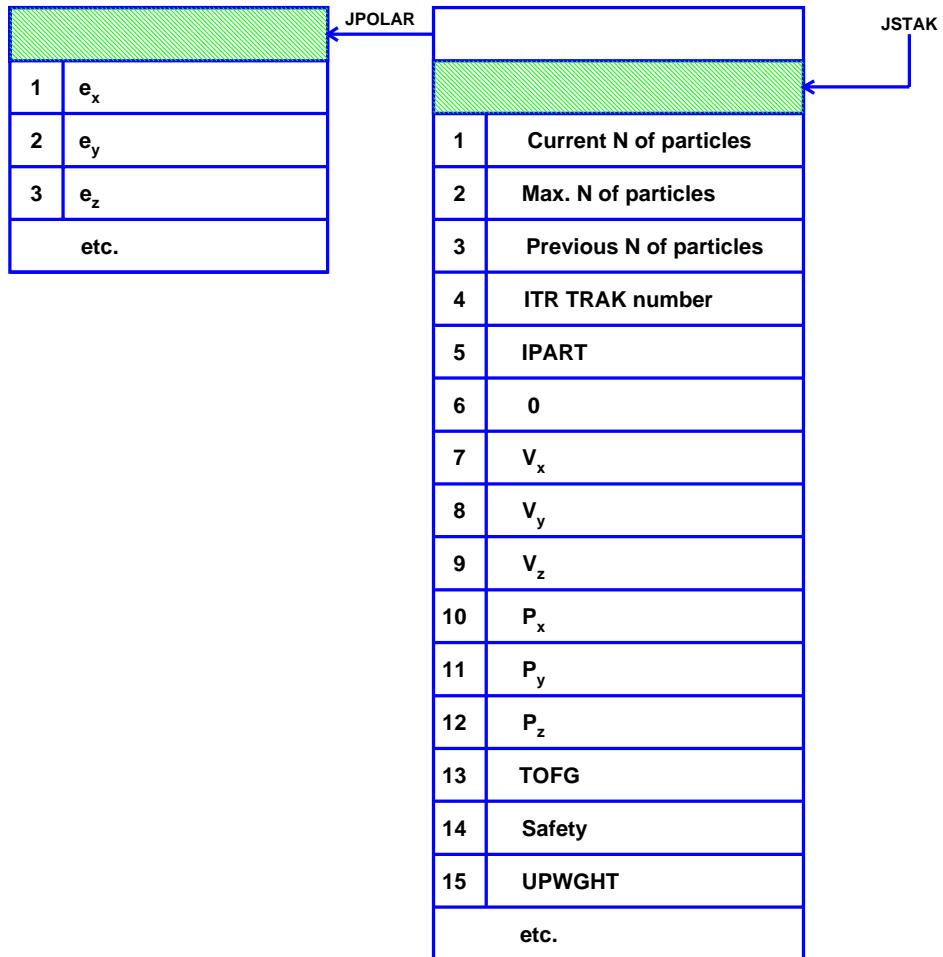

Figure 58: Layout of the temporary stack data structure `JSTAK`

The `JSTAK` bank is filled by `GSKING`.

Handling of track space points

    CALL **GSXYZ**

Stores the position of the current particle from common `/GCTRAK/` into the data structure `JXYZ`.

    CALL **GPJXYZ** `(NUMB)`

`NUMB`   (`INTEGER`) track number, all tracks if =0;

Prints space points stored in the data structure `JXYZ` for track number `NUMB`.

    CALL **GPCXYZ**

Prints tracking and physics parameters after the current step. This routine can be called from `GUSTEP`.

Some of these routines are called by `GDEBUG`, see `[BASE400]` for more information.

The space point data structure `JXYZ`
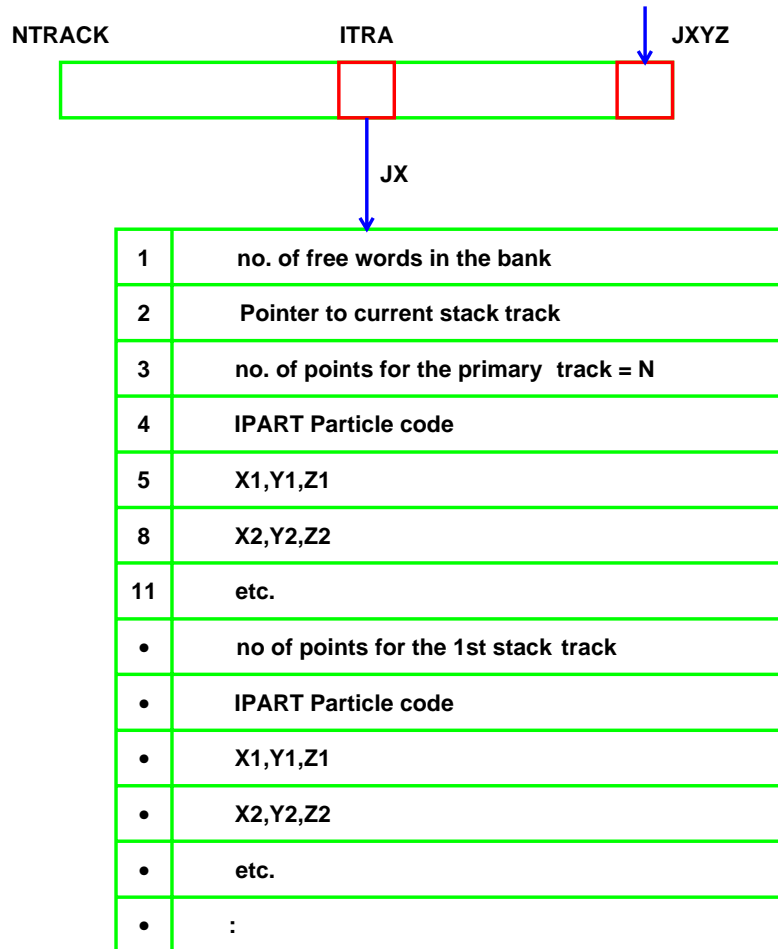

Figure 59: Layout of the `JXYZ` data structure

`JX=LQ(JXYZ-ITRA)` is the pointer to the space points of track number `ITRA`

The space point banks `JXYZ` are only used for debug and display purposes. They can be filled by using the routine `GSXYZ` from `GUSTEP`. The drawing routine `GDXYZ` gets the space coordinates from `JXYZ`.

Tracking routines in magnetic field

> CALL **GUSWIM** (CHARGE,STEP,VECT,VOUT*)

CHARGE   (REAL) particle charge in e unit;
STEP   (REAL) step size in cm;
VECT   (REAL) array of 7 with the initial coordinates, direction cosines and momentum (x, y, z, p_x/p, p_y/p, p_z/p, p);
VOUT   (REAL) array of 7 with the final coordinates, direction cosines and momentum after the step.

This is the steering routine for calculating the deviation of a charged particle in magnetic field. It is called by the GEANT tracking routines: GTELEC, GTHADR, GTMUON and GTHION. Even if this routine follows the naming conventions of the user routines, the version provided in the GEANT library is quite adequate for most situation, and users should have a very good reason to modify it.

It calls GRKUTA, GHELIX, GHELX3 according to the value 1, 2 or 3 of IFIELD in common /GCTMED/. IFIELD correspond to the argument to the GSTMED routine (see [CONS200]). IFIELD = -1 is reserved for user decision in case GUSWIM is modified by the user.

> CALL **GHELX3** (FIELD,STEP,VECT,VOUT*)

FIELD   (REAL) field value in kilo-Gauss multiplied by the charge of the particle in e units;
STEP   (REAL) step size in cm;
VECT   (REAL) array of 7, same as for GUSWIM;
VOUT   (REAL) array of 7, same as for GUSWIM;

Transport the particle by a length STEP in a magnetic field. The field is assumed to be uniform and parallel to the z axis. The value of the field is the FIELDM argument to the GSTMED routine (see [CONS200]). The particle is transported along an helix. The call to this routine is selected by GUSWIM when IFIELD=3 in the call to GSTMED.

> CALL **GHELIX** (CHARGE,STEP,VECT,VOUT*)

CHARGE   (REAL) particle charge in e units;
STEP   (REAL) step size in cm;
VECT   (REAL) array of 7, same as for GUSWIM;
VOUT   (REAL) array of 7, same as for GUSWIM;

Transport the particle by a length STEP in a magnetic field. The magnetic field is calculated in the middle of the step (along a straight line) and it is supposed to be constant along the step and the particle is transported along an helix. The call to this routine is selected by GUSWIM when IFIELD=2 in the call to GSTMED. This routine is intended for magnetic fields with a small gradient. The value of the field is obtained from the routine GUFLD which must be coded by the user.

> CALL **GRKUTA** (CHARGE,STEP,VECT,VOUT*)

The arguments have the same meaning than those of GHELIX. Transport a particle in magnetic field using Runge-Kutta method for solving the kinematic equations (Nystroem algorithm [1], procedure 25.5.20). The call to this routine is selected by GUSWIM when IFIELD=1 in the call to GSTMED. This method is the slower of

the three and it must be used for magnetic fields with strong gradient. Again the magnetic field is obtained from the `GUFLD` routine which the user has to code.

```
CALL GUFLD  ((VECT,F*)
```

VECT   (`REAL`) array of 3 with the position in space where the field has to be returned;

F   (`REAL`) array of 3 with the magnetic field in `VECT`, in kilo-Gauss units.

User routine to return the three components of the magnetic field at point `VECT` expressed in kilo-Gauss. This routine must be provided by the user for all tracking media where `IFIELD` is 1 or 2. This routine will be called very often, at least three times at each step, so all the care must be put in its optimisation.

TRAK Bibliography

[1] Handbook. Technical report, National Bureau of Standards.

The interactive version of `GEANT`

The interactive version is an essential tool for users who are in charge of the design of a detector. In addition to all the batch tools which are also available, the interactive user can call one by one and in any order all the basic functions of `GEANT` to:

- design or modify the geometry of the setup;

- exploit the drawing package in a more efficient way;

- change the running conditions on a event by event basis.

The system is based on the `KUIP` [1] command processor. The user has to know a minimum about `KUIP` and should read at least the first chapter of the manual.

A set of encapsulated Postscript files have been collected in a new section XINT010. They illustrate the visualization possibilities of the interactive version of `GEANT`.

1 Invoking the interactive version

Instead of writing a MAIN program to initialize the Geant batch version, it is possible to use the MAIN interactive program (GXINT321.F) provided in /cern/pro/lib exactly as the library LIBGEANT321.A. The user has simply to insert in his link file the file GXINT321.F as the main program, followed by the user object code and by the library LIBGEANT321.A.

Example:
PROGRAM GXINT
*
* GEANT main program. To link with the MOTIF user interface
* the routine GPAWPP(NWGEAN,NWPAW) should be called, whereas
* the routine GPAW(NWGEAN,NWPAW) gives access to the basic
* graphics version.
*
PARAMETER (NWGEAN=3000000,NWPAW=1000000)
COMMON/GCBANK/GEANT(NWGEAN)
COMMON/PAWC/PAW(NWPAW)
*
CALL GPAWPP(NWGEAN,NWPAW)
*
END

The user has to set the desired value of NWGEAN and NWPAW for the GEANT and PAW Zebra stores, and to call the desired initialization routine:

- GPAW to initialize, besides GEANT, also HIGZ and to include the full functionality of PAW;

- GPAWPP to initialize, besides GEANT and HIGZ, also the Motif version and to include the full functionality of Paw++;

- USER initialization routine, to do anything else (for example a UGINIT- like routine or a gxint315.f–like routine).

The interactive version, after the initialization, gives the control to the user at the prompt GEANT > ; then it is possible to type and execute commands (corresponding to batch routines) to edit the geometry, the materials or the tracking media at run time. It is also possible to execute commands to visualize the detectors, to set the kinematics and to run events. Again interactively, one can spy the histograms, change the kinematics, and run more events (visualizing the tracks and the hits, for example). The GXINT chapter contains in the following pages a full description of the available GEANT commands. See the PAW, KUIP, DZDOC, HIGZ manuals for a description of the relative commands executable from GEANT. All the commands are also documented by an on-line help. (Try to type HELP at the first GEANT > prompt). In the interactive version, a COMIS interface is also available: COMIS is a FORTRAN interpreter which allows:

- to edit at run time important routines like UGEOM, GUSTEP, GUKINE, etc.

- to 'execute' them from the interactive session, without having to recompile and relink, by typing commands like CALL UGEOM.F.

Of course the interpreter is slower than the compiled object code, then, since GEANT321, it is also possible to invoke the native compiler and to link dinamically to the executable the compiled routine (see the COMIS manual for further details).

The following write ups describe individual commands which can be typed one by one at the terminal, or grouped into macros which can be edited and saved in the KUIP environment.

The commands are listed in subsection 1 - 13:

1. General GEANT
2. Clipping commands GEANT/CVOL
3. Drawing commands GEANT/DRAWING
4. Graphics control commands GEANT/DRAWING
5. Geometry commands GEANT/GEOMETRY
6. Volume creation commands GEANT/CREATE
7. Control commands GEANT/CONTROL
8. ZEBRA/RZ commands GEANT/RZ
9. ZEBRA/FZ commands GEANT/FZ
10. Data structure commands GEANT/DZ
11. Scanning commands GEANT/SCAN
12. Physics parameter commands GEANT/PHYSICS
13. List commands GEANT/LISTS

2   The Motif Interface

The interactive version 3.21 contains an object oriented Motif-based user interface. It can be accessed specifying 'm' as workstation type. The full functionality of the X11 version remains available, while new Motif-specific features have been added.

3   The main ideas

The GEANT data structures are considered as KUIP browsable classes and their contents as 'objects' on which one can perform actions (the GEANT commands). According to the Motif conventions, an object can be selected clicking the left button of the mouse (when the cursor is on the icon representing that object).

Clicking then on the right button of the mouse, a menu of possible commands will appear (double clicking on the left button the first action of this list will be executed); the selected command will perform the relative actions on the selected object. Such actions (like drawing, for example) can be executed either directly or via the use of an automatically opened Motif panel. Objects drawn in the graphics window can be 'picked' as well (for example, volumes, tracks, hits); clicking the right button when the cursor is on the selected object, a menu of possible actions on that object is displayed. Users can finally define Motif panels containing buttons corresponding to the most frequently used commands. An on-line help is available for any specific subject.

4   The Geant++ Executive Window

It replaces the normal dialog window; it contains a Transcript Pad, where the text output of the executed commands is displayed, and an Input Pad, where the user can still type the desired commands in the old style.

The `Geant++` Main File Browser

On the left side it displays a list of the `GEANT` data structures, of the available commands, file, macros and Zebra divisions used. Selecting one of them, the full list of icons representing the objects of that class is shown in the main area of the browser. Proceeding as described before, it is possible to perform actions on the classes (like create a new object) or on the objects belonging to them. It is possible to create menus of commands just clicking on the string 'commands' at the top line of the browser.

The Geant++ Graphics Window

Any object to be drawn in the graphics window can be stored in the current picture file (automatically opened after each NEXT command) via a call to IGPID (see Higz manual). It can be afterwards 'picked' as described before. In the case of commands executed via the use of Motif panels, some input values can be set with a slider ranging in the specifed range for the relative variable; moving the slider (after having clicked on the right-hand 'activating box') the relative action is performed in the graphics window when releasing the button of the mouse; when in 'drag mode', the action is performed *while* moving the slider (keeping the left button pressed): especially when double buffering has been selected, this can be useful for real time manipulations.

5   An Example

Start your `GEANT321` executable module (linked with GXINT321 and Motif1.2);

type 'm' as workstation type;

click the left button of the mouse after positioning the cursor on the string VOLU in the browser;

click the left button of the mouse after positioning the cursor on any icon in the main area of the browser;

click now the right button of the mouse and keep it pressed;

move the mouse to select the action 'Tree' and release the button;

the drawing of the logical tree will be displayed in the graphics window;

position the cursor on the drawing of a box (containing a volume name) in the graphics window, click the right button and keep it pressed;

release the button selecting the action 'Dspec';

the command DSPEC for that volume will be executed in a separate window;

repeat the exercise selecting this time the action 'Dspe3d';

the DSPEC will be executed in the first window, the volume specifications will be printed in a separate window and a Motif panel will appear;

click the left button of the mouse positioning the cursor in the Motif panel on the 'Value changed' button, and select the DRAG option;

click now the left button on the 'activating box' on the right of the 'Theta' slider;

click on the 'Theta' slider and, keeping pressed the left button of the mouse, move it right-wards;

the drawing in the graphics window will rotate;

release the button and type 'igset 2buf 1' in the executive window;

restart moving the slider as before.

Introduction to the Interactive version of GEANT

1   GEANT

GEANT specific commands.

2   GEANT/CVOL

Clipping commands. The hidden line removal technique is necessary to visualize properly very complex detectors. At the same time, it can be useful to visualize the inner elements of a detector in detail. For this purpose, the commands menu CVOL has been developed: these commands allow subtractions (via boolean operation) of given shapes from any part of the detector, therefore showing its inner contents. It is possible to clip each different volume by means of a different shape (BOX , TUBE, CONE, SPHE are available). If '*' is given as the name of the volume to be clipped, all volumes are clipped by the given shape. A volume can be clipped at most twice (even by different shapes); if a volume is explicitly clipped twice, the '*' will not act on it anymore. Giving '.' as the name of the volume to be clipped will reset the clipping.

2.1   BOX cnnv [xmin xmax ymin ymax zmin zmax]

```
CNNV   C   " Name of volume to be clipped "  D='* '
XMIN   R   " Lower limit of the Shape X coordinate "  D=-10000.
XMAX   R   " Upper limit of the Shape X coordinate "  D=-9999.
YMIN   R   " Lower limit of the Shape Y coordinate "  D=-10000.
YMAX   R   " Upper limit of the Shape Y coordinate "  D=-9999.
ZMIN   R   " Lower limit of the Shape Z coordinate "  D=-10000.
ZMAX   R   " Upper limit of the Shape Z coordinate "  D=-9999.
```

This command performs a boolean subtraction between the volume CNVV and a box placed in the MARS according the values of the given coordinates. See also CVOL. The following commands will clip by a box, with a vertex at the origin, the volume specified by NAME (a valid string for the NAME of the volume can be found using the DTREE command).

```
EXAMPLE -
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
next
box NAME 0 1000 0 1000 0 1000
draw NAME 40 40 0 10 10 .01 .01
box .
```

2.2   TUBE cnvv [rmax zdem xmed ymed zmed]

```
CNVV   C    " Name of volume to be clipped "  D='* '
```

```
RMAX    R    " External radius of tube "   D=0.1
ZDEM    R    " Half length of tube axis "   D=0.1
XMED    R    " Center X coordinate "   D=-10000.
YMED    R    " Center Y coordinate "   D=-10000.
ZMED    R    " Center Z coordinate "   D=-10000.
```

This command performs a boolean subtraction between the volume CNVV and a tube; the tube has the given parameters and is placed in the MARS according the given coordinates of its center. See also CVOL. The following commands will clip, by a tube, positioned according to the given parameters, the volume specified by NAME (a valid string for the NAME of the volume can be found using the DTREE command).

```
EXAMPLE -
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
next
tube * 500 1000 500 0 0
draw NAME 40 40 0 10 10 .01 .01
box .
```

2.3   CONE cnvv [rmax1 rmax2 zdem xmed ymed zmed]

```
CNVV     C    " Name of volume to be clipped "   D='* '
RMAX1    R    " Min external radius "   D=0.1
RMAX2    R    " Max external radius "   D=0.1
ZDEM     R    " Half length of cone axis "   D=0.1
XMED     R    " Center X coordinate "   D=-10000.
YMED     R    " Center Y coordinate "   D=-10000.
ZMED     R    " Center Z coordinate "   D=-10000.
```

This command performs a boolean subtraction between the volume CNVV and a cone; the cone has the given parameters and is placed in the MARS according to the given coordinates of its center. See also CVOL. The following commands will clip by a cone, positioned according the given parameters, the volume specified by NAME (a valid string for the NAME of the volume can be found using the DTREE command).

```
EXAMPLE -
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
next
cone * 1 750 1000 0 0 1000
draw NAME 40 40 0 10 10 .01 .01
box .
```

2.4   SPHE cnvv [rmax xmed ymed zmed]

```
CNVV    C    " Name of volume to be clipped "   D='* '
RMAX    R    " External radius of sphere "   D=0.1
XMED    R    " Center X coordinate "   D=-10000.
```

```
YMED   R   " Center Y coordinate "  D=-10000.
ZMED   R   " Center Z coordinate "  D=-10000.
```

This command performs a boolean subtraction between the volume CNVV and a sphere; the sphere has the given parameters and is placed in the MARS according to the given coordinates of its center. See also CVOL. The following commands clip by a sphere, positioned according to the given parameters, the volume specified by NAME (a valid string for the NAME of the volume can be found using the DTREE command). EXAMPLE -

```
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
next
sphe * 500 0 0 500
draw NAME 40 40 0 10 10 .01 .01
box .
```

2.5   VALCUT xcut ycut zcut

```
XCUT   R   "x coordinate of cutted value"  D=0.
YCUT   R   "y coordinate of cutted value"  D=0.
ZCUT   R   "z coordinate of cutted value"  D=0.
```

It allows the cutting in the ray-tracing. All the volumes are cutted from XCUT to +BIG along the x axis, from YCUT to +BIG along the y axis and from ZCUT to +BIG along the z axis.

3 GEANT/DRAWING

Drawing commands. These commands allow the visualization in several ways of the volumes defined in the geometrical data structure. It is possible to draw the logical tree of volumes belonging to the detector (DTREE), to show their geometrical specification (DSPEC,DFSPC), to draw them and their cut views (DRAW, DCUT). Moreover, it is possible to execute these commands when the hidden line removal option is activated; in this case, the volumes can be also either translated in the space (SHIFT), or clipped by boolean operation (CVOL). In addition, it is possible to fill the surfaces of the volumes with solid colours when the shading option (SHAD) is activated. Several tools (ZOOM, LENS) have been developed to zoom detailed parts of the detectors or to scan physical events as well. Finally, the command MOVE will allow the rotation, translation and zooming on real time parts of the detectors or tracks and hits of a simulated event. Ray-tracing commands. In case the command (DOPT RAYT ON) is executed, the drawing is performed by the Geant ray-tracing; automatically, the color is assigned according to the tracking medium of each volume and the volumes with a density lower/equal than the air are considered transparent; if the option (USER) is set (ON) (again via the command (DOPT)), the user can set color and visibility for the desired volumes via the command (SATT), as usual, relatively to the attributes (COLO) and (SEEN). The resolution can be set via the command (SATT * FILL VALUE), where (VALUE) is the ratio between the number of pixels drawn and 20 (user coordinates). Parallel view and perspective view are possible (DOPT PROJ PARA/PERS); in the first case, we assume that the first mother volume of the tree is a box with dimensions 10000 X 10000 X 10000 cm and the view point (infinetely far) is 5000 cm far from the origin along the Z axis of the user coordinates; in the second case, the distance between the observer and the origin of the world reference system is set in cm by the command (PERSP NAME VALUE); grand-angle or telescopic effects can be achieved changing the scale factors in the command (DRAW). When the final picture does not occupy the full window, mapping the space before tracing can speed up the drawing, but can also produce less precise results; values from 1 to 4 are allowed in the command (DOPT MAPP VALUE), the mapping being more precise for increasing (VALUE); for (VALUE = 0) no mapping is performed (therefore max precision and lowest speed). The command (VALCUT) allows the cutting of the detector by three planes ortogonal to the x,y,z axis. The attribute (LSTY) can be set by the command SATT for any desired volume and can assume values from 0 to 7; it determines the different light processing to be performed for different materials: 0 = dark-matt, 1 = bright-matt, 2 = plastic, 3 = ceramic, 4 = rough-metals, 5 = shiny-metals, 6 = glass, 7 = mirror. The detector is assumed to be in the dark, the ambient light luminosity is 0.2 for each basic hue (the saturation is 0.9) and the observer is assumed to have a light source (therefore he will produce parallel light in the case of parallel view and point-like-source light in the case of perspective view).

3.1 DRAW name [theta phi psi u0 v0 su sv]

```
NAME    C   "Volume name"
THETA   R   "Viewing angle theta (for 3D projection)"  R=0.:180.
PHI     R   "Viewing angle phi (for 3D projection)"  R=0.:360.
PSI     R   "Viewing angle psi (for 2D rotation)"  R=0.:360.
U0      R   "U-coord. (horizontal) of volume origin"
V0      R   "V-coord. (vertical) of volume origin"
SU      R   "Scale factor for U-coord."
SV      R   "Scale factor for V-coord."

CALL GDRAW(name,theta,phi,psi,u0,v0,su,sv)
```

If optional parameters are missing, the corresponding values are taken from the common /GCDRAW/. This command will draw the volumes, selected with their graphical attributes, set by the SATT facility. The drawing may be performed with hidden line removal and with shading effects according to the value of the options HIDE and SHAD; if the option SHAD is ON, the contour's edges can be drawn or not. If the option

HIDE is ON, the detector can be exploded (BOMB), clipped with different shapes (CVOL), and some of its parts can be shifted from their original position (SHIFT). When HIDE is ON, if the drawing requires more than the available memory, the program will evaluate and display the number of missing words (so that the user can increase the size of its ZEBRA store). Finally, at the end of each drawing (with HIDE on), the program will print messages about the memory used and statistics on the volumes' visibility. The following commands will produce the drawing of a green volume, specified by NAME, without using the hidden line removal technique, using the hidden line removal technique, with different linewidth and colour (red), with solid colour, with shading of surfaces, and without edges. Finally, some examples are given for the ray-tracing. (A possible string for the NAME of the volume can be found using the command DTREE).

```
EXAMPLE -

draw NAME 40 40 0 10 10 5 5
```

3.2   SPOT xlpos ylpos zlpos inten

XLPOS	R	"x coordinate of light source"
YLPOS	R	"y coordinate of light source"
ZLPOS	R	"z coordinate of light source"
INTEN	I	"intensity of light source"

This point-like light source can be moved in the space and its intensity can be changed (INTEN going from 0 to 10) relatively to the ambience light.

3.3 VAR5D tseqto nproc nmptot totmby tseq tlat tnet

TSEQTO	R	"total sequential time"
NPROC	I	"number of processors"
NMPTOT	I	"number of message passing"
TOTMBY	R	"total megabytes transfert"
TSEQ	R	"not parallelized code"
TLAT	R	"latency time"
TNET	R	"network speed in Mbytes/sec"

It sets the values of the parameters expressed in the formula and specify which variables must be assumed as x,y,z (setting their value to 1001,1002,1003, respectively).

3.4 RANG5D x1min x1max y1min y1max z1min z1max

X1MIN	R	"x coordinate min"
X1MAX	R	"x coordinate max"
Y1MIN	R	"y coordinate min"
Y1MAX	R	"y coordinate max"
Z1MIN	R	"z coordinate min"
Z1MAX	R	"z coordinate max"

It sets the range for the x,y,z variables.

3.5 DVOLUME n namnum chnrs [theta phi psi u0 v0 su sv]

N	I	"Number of elements in arrays LNAMES and LNUMBS" D=1
NAMNUM	C	"Volume names and numbers (ex. "NAME1,NR1,NAME2,NR2")"
CHNRS	C	"Reference system used" D='MARS'
THETA	R	"Viewing angle theta (for 3D projection)" R=0.:360.
PHI	R	"Viewing angle phi (for 3D projection)" R=0.:360.
PSI	R	"Viewing angle psi (for 2D rotation)" R=0.:180.
U0	R	"U-coord. (horizontal) of volume origin"
V0	R	"V-coord. (vertical) of volume origin"
SU	R	"Scale factor for U-coord."
SV	R	"Scale factor for V-coord."

Possible CHNRS values are:
 MARS

 DRS

```
CALL GDRVOL(n,lnames,lnumbs,nrs,theta,phi,psi,u0,v0,su,sv)
```

N is the number of levels from the top of the geometry structure to the volume lnames(n),lnumbs(n) to be drawn. NAMNUM contain the arrays lnames and lnumbs, identifying the path, in pairs and separated

by commas; for example (with n=2) : 'lname(1),lnumbs(1),lname(2),lnumbs(2) ' CHNRS is the name of the reference system used: MARS for MAster Reference System or DRS for Daughter Reference System. NRS=0 for MARS or NRS⟨⟩0 for DRS If optional parameters are missing, the current values in /GCDRAW/ are taken.

3.6   DCUT name caxis cutval [u0 v0 su sv]

NAME	C	"Volume name"
CAXIS	C	"Axis value"
CUTVAL	R	"Cut plane distance from the origin along the axis"
U0	R	"U-coord. (horizontal) of volume origin"
V0	R	"V-coord. (vertical) of volume origin"
SU	R	"Scale factor for U-coord."
SV	R	"Scale factor for V-coord."

Possible `CAXIS` values are:

 X

 Y

 Z

```
CALL GDRAWC(name,iaxis,cutval,u0,v0,su,sv)
```

The cut plane is normal to caxis (X,Y,Z), corresponding to iaxis (1,2,3), and placed at the distance cutval from the origin. The resulting picture is seen from the the same axis. If optional parameters are missing, the current values in /GCDRAW/ are taken. When HIDE Mode is ON, it is possible to get the same effect with the CVOL/BOX command.

3.7   DXCUT name cutthe cutphi cutval [theta phi u0 v0 su sv]

NAME	C	"Volume name"
CUTTHE	R	"Theta angle of the line normal to cut plane" R=0.:360.
CUTPHI	R	"Phi angle of the line normal to cut plane" R=0.:360.
CUTVAL	R	"Cut plane distance from the origin along the axis"
THETA	R	"Viewing angle theta (for 3D projection)" R=0.:360.
PHI	R	"Viewing angle phi (for 3D projection)" R=0.:360.
U0	R	"U-coord. (horizontal) of volume origin"
V0	R	"V-coord. (vertical) of volume origin"
SU	R	"Scale factor for U-coord."
SV	R	"Scale factor for V-coord."

```
CALL GDRAWX(name,cutthe,cutphi,cutval,theta,phi,u0,v0,su,sv)
```

The cut plane is normal to the line given by the cut angles cutthe and cutphi and placed at the distance cutval from the origin. The resulting picture is seen from the viewing angles theta,phi. If optional parameters are missing, the current values in /GCDRAW/ are taken.

3.8   SHIFT cnvn xxxx yyyy zzzz

```
CNVN   C   " Name of volume to be shifted "  D='*'
XXXX   R   " Shift along X axis "  D=0.
YYYY   R   " Shift along Y axis "  D=0.
ZZZZ   R   " Shift along Z axis "  D=0.
```

To draw a volume shifted from its initial position when hidden line removal is ON. It can be useful if you want to extract a volume or some volumes from the detector to show them more clearly. The last requested SHIFT for each volume NAME is performed. Moreover, the SHIFT of each volume will be performed starting from where its mother has been shifted, so that it's easier to SHIFT nicely sets of volumes using the mother-daughter relationships. If '.' is given as the name of the volume to be shifted, the shifts for all volumes will be reset. The following commands will produce the translation along the Z-axis of the previously drawn volume:

```
EXAMPLE -
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
shift NAME 0 0 10
```

3.9   BOMB boom

```
BOOM   R   " Exploding factor for volumes position "  D=0.   R=-10.:10.
```

To 'explode' the detector. If BOOM is positive (values smaller than 1. are suggested, but any value is possible) all the volumes are shifted by a distance proportional to BOOM along the direction between their centre and the origin of the MARS; the volumes which are symmetric with respect to this origin are simply not shown. BOOM equal to 0 resets the normal mode. A negative (greater than -1.) value of BOOM will cause an 'implosion'; for even lower values of BOOM the volumes' positions will be reflected respect to the origin. This command can be useful to improve the 3D effect for very complex detectors. The following commands will make explode the detector:

```
EXAMPLE -
dopt hide on
satt * seen 1
draw NAME 40 40 0 10 10 .01 .01
bomb 1
next
draw NAME 40 40 0 10 10 .01 .01
```

3.10   DTREE [name levmax iselt]

```
NAME     C   "Volume name"  D=' '
LEVMAX   I   "Depth level"  D=3 R=-15:15
ISELT    I   "Options "  D=111
```

This command allows the drawing of the logical tree, displaying the name, the multiplicity and other information about the volumes, via a call to GDTREE(name,levmax,isel): if the third parameter is not given (default), the command will produce the drawing of the tree displaying, for each volume, the number of the following levels (red arrows) and of the preceeding levels (green arrows); then the control is automatically given to the mouse: clicking on the left button when the cursor is inside a volume's pave will perform a

DSPEC for that volume; doing the same when the cursor is on a red arrow, will perform a DTREE for the relative volume (the number of levels displayed depending on the clicked arrow); doing the same for the 'i-th' green arrow of a given volume, will perform a DTREE for its mother-volume staying 'i' levels before. If running with X-windows, the drawing of the specification (DSPEC) is performed in a different window to speed up the scanning of the tree. Iterating this procedure it is possible to analyse very easily and quickly any kind of tree. Clicking the right button of the mouse will return the control to the command mode. If the ISELT parameter is given, then the TREE will work as in the previous version, with ISELT up to 10001. The following command will perform a drawing of the tree and give the control to the user via the mouse:

```
EXAMPLE -
dtree NAME 3
```

3.11   DSPEC name

```
 NAME   C   "Volume name"
```

Trough a call to GDSPEC(name), this command allows one to show three views of the volume (two cut-views and a 3D view), together with its geometrical specifications. The 3D drawing will be performed according the current values of the options HIDE and SHAD and according the current CVOL clipping parameters for that volume.

3.12   D3DSPEC name [teta3 phi3 psi3 u03 v03 zm3]

```
NAME    C   "Volume name"
TETA3   R   "Theta angle"  D=40.   R=0.:180.
PHI3    R   "Phi angle"  D=40.   R=0.:360.
PSI3    R   "Psi angle"  D=0.   R=0.:360.
U03     R   "U-coord. (horizontal) of volume origin"  D=10.   R=-40.:40.
V03     R   "V-coord. (vertical) of volume origin"  D=10.   R=-40.:40.
ZM3     R   "Zoom factor for current size factors"  D=1.   R=0.00001:10.
```

Trough a call to GSPE3D, this command allows one to show the volume (3D views in real time), together with its geometrical specifications (if using MOTIF). The 3D drawing will be performed according the current values of the options HIDE and SHAD and according the current CVOL clipping parameters for that volume.

3.13   DFSPC name [csort cinter]

```
NAME     C   "Volume name"
CSORT    C   "Alphabetic sorting flag"  D='N'
CINTER   C   "Interactive/Batch version"  D='I'
```

Possible CSORT values are:

 Y

 N

 0

 1

Possible CINTER values are:

```
I

B

O

1
```

```
    CALL GDFSPC(name,isort,inter)
```

Same as DSPEC, but it will draw the specifications for all the volumes. If the alphabetic sorting flag is YES, all pictures will be drawn in ascending alphabetic order; isort is set to 1. If INTERACTIVE, (inter=1), the routine will prompt the user at each plot before doing a clear screen, otherwise it will clear automatically the screen before starting a new frame.

3.14   DTEXT x0 y0 text size angle lwid cent

```
    XO      R   "X-coord. (horizontal) of text string"  D=10.   R=0.:20.
    YO      R   "Y-coord. (vertical) of text string"  D=10.   R=0.:20.
    TEXT    C   "Text string"  D='GEANT'
    SIZE    R   "Character size (cm)"  D=.5
    ANGLE   R   "Rotation angle (deg)"  D=0.   R=0.:360.
    LWID    I   "Line width"  D=4
    CENT    C   "Centering option"  D='CENT'
```

Possible CENT values are:
```
 CENT

 LEFT

 RIGH
```

```
    CALL GDRAWT(xO,yO,text,size,angle,lwid,opt)
```

It allows one to draw some text in the current picture. Now more than 160 colours are available. The text colour must be set via the command IGSET. The size of the text will follow the zooming factors in the view banks.

3.15   DVECTOR xvect yvect npoint

```
    XVECT    C   "Vector containing X-coord. (horizontal)"
    YVECT    C   "Vector containing Y-coord. (vertical)"
    NPOINT   I   "Number of coord."
```

Draw a polyline of 'npoint' point via a call to GDRAWV(xvect,yvect,npoint) where xvect and yvect are two KUIP vectors

3.16   DSCALE u v

```
    U   R   "U-coord. (horizontal) of the centre of scale"
    V   R   "V-coord. (vertical) of the centre of scale"
```

```
CALL GDSCAL(u,v)
```

It draws a scale centered in U,V.

3.17   DAXIS x0 y0 z0 dx

```
X0   R   "X-coord. of axis origin"
Y0   R   "Y-coord. of axis origin"
Z0   R   "Z-coord. of axis origin"
DX   R   "Axis size"
```

```
CALL GDAXIS(x0,y0,z0,dx)
```

This commmand superimposes the axis of the MARS on the current picture. It is useful for finding immediately the orientation of the current drawing of the detector in the space.

3.18   DMAN u v type

```
U      R   "U-coord. (horizontal) of the centre of man"
V      R   "V-coord. (vertical) of the centre of man"
TYPE   C   "Man, Wm1, Wm2, Wm3"  D='MAN'
```

Possible TYPE values are:
```
MAN

WM1

WM2

WM3
```

```
CALL GDMAN(u,v),CALL GDWMN1(u,v),CALL GDWMN2(u,v),CALL GDWMN2(u,v)
```

It superimposes the picure of a man or of a woman, chosen among three different ones, with the same scale factors as the detector in the current drawing.

3.19   DHEAD [isel name chrsiz]

```
ISEL     I   "Option flag"  D=111110
NAME     C   "Title"  D=' '
CHRSIZ   R   "Character size (cm) of title NAME"  D=0.6
```

```
CALL GDHEAD(isel,name,chrsiz)
```

ISEL =

```
0      to have only the header lines
xxxxx1 to add the text name centered on top of header
xxxx1x to add global detector name (first volume) on left
xxx1xx to add date on right
xx1xxx to select thick characters for text on top of header
```

```
x1xxxx to add the text 'EVENT NR x' on top of header
1xxxxx to add the text 'RUN NR x' on top of header
```

NOTE that ISEL=x1xxx1 or ISEL=1xxxx1 are illegal choices, i.e. they generate overwritten text. NAME is the title and CHRSIZ the character size in cm of text name.

3.20   MEASURE

Position the cursor on the first point (u1,v1) and hit the space bar(GKS). Position the cursor on the second point (u2,v2) and hit the space bar(GKS). Clicking the left button of the mouse (X11) will have the same effect as hiting the space bar (GKS). The command will compute and print the distance in space separating the two points on the projection view. It can be useful to measure distances either between volumes or between tracks or hits.

3.21   PICK

Activates graphic input to identify detector elements in a cut view. Clicking on the left button of the mouse when the cursor is in a given point of the drawing and clicking again (outside the detector) will produce the following effect: a line joininig the two points will be drawn together with the name and the medium number of the volume picked with the first clicking close to the second point.

3.22   MOVE name [nopt]

```
NAME   C   "Volume name"  D=' '
NOPT   C   "S=sample mode,T=tracks,H=hits"  D=' '
```

Positioning some daughter volumes inside a 'mother', it can be important to check if overlaps between such volumes have occurred. Instead of putting the drawing in a view bank, zooming, and iterating the process for different viewing angles of the same detector, the MOVE facility has been developed (for machines running with X11): it is sufficient to draw a view of the volumes to be analysed (after setting the proper SEEN, COLO, etc. attributes) and then to enter 'MOVE' followed by the same 'NAME' used for the last command DRAW. The detector will appear in a panel with five buttons at the bottom: THETA, PHI, TRASL, ZOOM, OFF. Clicking on the left button of the mouse, when the cursor is inside the THETA area, will rotate the detector along the polar angle theta according to the backward-to-forward movement of the mouse (clicking up and down the left button if not in sample mode); clicking on the right button of the mouse will stop the rotation; clicking now on the left button of the mouse when inside the PHI area will activate a rotation along the polar angle phi. In the same way, activating the TRASL button, the detector can be translated in the u,v plane of the screen according to the 2D-movement of the mouse. Finally, activating the ZOOM button, the detector will be zoomed (or unzoomed) according to the backward-to-forward movement of the mouse. Clicking on the OFF button will return the control to the 'command mode'. The MOVE command will work also with hidden line removal and shading options (when SHAD is on the background will be black); moreover, if the volumes are clipped, exploded, shifted, etc., they will be 'MOVED' with these features as well. Tracks and hits of a previously stored physical event can be moved together with the detector, allowing a dynamical 3-D analysis of the simulated events. Clicking the central button of the mouse when a good view of the event is found, will stop any movement and the mouse will allow the normal picking capabilities first for the tracks and then for the hits. After clicking of the right button, the normal movement will restart to find another interesting view of the event and to iterate the process. The MOVE is also available in sample mode. The following commands will produce a drawing of a volume and then will give the control to the MOVE panel; try the following possibilities:

```
EXAMPLE 1 -
dopt hide off
satt * seen -2
```

```
draw NAME 40 40 0 10 10 .01 .01
move NAME
EXAMPLE 2 -
dopt hide on
satt * seen -2
draw NAME 40 40 0 10 10 .01 .01
move NAME
EXAMPLE 3 -
dopt shad on
satt * colo 3
satt * fill 2
dopt edge off
draw NAME 40 40 0 10 10 .01 .01
move NAME
```

3.23   MOVE3D name [theta phi psi u0 v0 su sv sz nopt]

```
NAME    C   "Volume name"  D=' '
THETA   R   "Viewing angle theta (for 3D projection)"  D=40.   R=0.:180.
PHI     R   "Viewing angle phi (for 3D projection)"  D=40.   R=0.:360.
PSI     R   "Viewing angle psi (for 2D rotation)"  D=0.   R=0.:180.
U0      R   "U-coord. (horizontal) of volume origin"  D=10.   R=0.:20.
V0      R   "V-coord. (vertical) of volume origin"  D=10.   R=0.:20.
SU      R   "Scale factor for U-coord."    D=0.01
SV      R   "Scale factor for V-coord."    D=0.01
SZ      R   "Scale zoom factor"  D=1.   R=0.1:10.
NOPT    C   "T=tracks,H=hits"  D=' '
```

Possible `NOPT` values are:
```
 T

 H
```
Same functionality of the command MOVE interfaced with MOTIF.

3.24   PERSP name distt [samp]

```
NAME    C   "Volume name"  D=' '
DISTT   R   "Volume distance from observer"  D=1000.
SAMP    C   "Control to the mouse"  D='OFF '
```

To control the perspective according to the variation of the distance between the observer and the object (if PROJ has the value PERS). If SAMP is ON the control of the distance is given via the mouse.

3.25   LENS knum [ksam]

```
KNUM    I   "View bank identifier"  D=1
KSAM    C   "Sample mode "  D='OFF '
```

Interactive zooming for detectors and events when running with X-windows. Using this command, when showing the contents of a view bank, it is possible to click (left button) in two points of the drawing (which will represent the left upper corner and the right bottom corner of the part to be zoomed). After the second click a new 'window' will appear to fit the frame defined by the two clicks and it will show a zoomed view as seen from a lens with those dimensions. Clicking now the central button will translate the lens over the drawing, while clicking the right button will stop it. Moreover, clicking the left button of the mouse, the lens will increase (or decrease) its magnification power according to the backward-to-forward movement of the mouse. A click on the right button will stop this action and it is possible to restart the translation of the lens or, clicking on the right button again, to make the lens disappear. It is then possible to open another 'window-lens' with different dimensions. Thus, this command can be useful to scan detailed parts of a detector or to scan hits and showers for events. Clicking the right button when no lens is displayed will return the control to the 'command mode'. The LENS is also available in sample mode when KSAM is 'ON'. The following commands will fill a view bank and will allow to scan the detector and an event previously stored via the use of LENS (when running with X-windows):

```
EXAMPLE -
satt * seen 1
dopen 1
draw NAME 40 40 0 10 10 .01 .01
dxyz 0
dhits * * 0 0 .2
dclose
dsh 1
lens 1 on
```

3.26   ZOOM [zfu zfv isel uz0 vz0 u0 v0]

ZFU   R   "Zoom factor for U-coord. (horizontal)" D=2.

ZFV   R   "Zoom factor for V-coord. (vertical)" D=2.

ISEL   I   "Options" D=1

UZ0   R   "U-coord. of the centre of zoom rectangle" D=10.   R=0.:20.

VZ0   R   "V-coord. of the centre of zoom rectangle" D=10.   R=0.:20.

U0   R   "U-coord. of the centre of resulting zoomed rectangle" D=10.   R=0.:20.

V0   R   "V-coord. of the centre of resulting zoomed rectangle" D=10.   R=0.:20.

```
CALL GDZOOM(zfu,zfv,uz0,vz0,u0,v0)
```

This command sets the zoom parameters that will be used by subsequent calls to the drawing routines. Each zoom operation is always relative to the status of the current zoom parameters. The scale factors in u,v are respectively zfu,zfv. zfu=0 (or zfv=0) will act as a reset (i.e. unzoomed viewing). The zoom is computed around uz0,vz0 (user coordinates), and the resulting picture will be centered at u0,v0. The use of the space bar is replaced by the left button of the mouse running with X11: If isel=0 :

```
1. position the cursor at (uz0,vz0)
2. type the space bar (GKS)
```

(u0,v0 are chosen at centre of screen) If isel=1 :

```
1. position the cursor at first corner of zoom rectangle
2. type the space bar (GKS)
3. position the cursor at second corner of zoom rectangle
4. type the space bar (GKS)
```

(zfu,zfv are chosen according to the zoom rectangle; uz0,vz0 are chosen at the centre of the zoom rectangle; u0,v0 are chosen at centre of screen) If isel=2 :

```
1. position the cursor at (uz0,vz0)
2. type the space bar (GKS)
3. position the cursor at (u0,v0)
4. type the space bar (GKS)
```

If isel=1000+n and running with X-windows:

```
1. n must be the identifier of an active view bank
2. clicking on the left button of the mouse will display
   a zoomed view (computed around the cursor position) of
   the previous drawing in a new window
3. it is now possible to iterate the zooming from the new window
4. clicking on the right button will return the control to the
   main window
5. clicking on the left button it is possible to open new windows
   zooming in other points of the detector
6. clicking on the right button when the main window is active
   will return the control to the 'command mode'.
```

3.27   DXYZ [itra]

```
ITRA   I   "Track number"  D=0
```

```
CALL GDXYZ(itra)
```

Draw tracks previously stored via GSXYZ.

3.28   KXYZ [epsilo]

```
EPSILO   R   "Delta angle"  D=0.25
```

```
CALL GKXYZ(epsilo)
```

The picking of track points requires the JXYZ data structure and is repeated until the character typed is 'Q' or 'q' (GKS) or the right button of the mouse is clicked (X11). EPSILO is the delta angle used for picking; if EPSILO=0 there is no optimization performed and over all the track points the one nearest to the pick point is taken.

3.29   DPART [itra isel size]

```
ITRA   I   "Track number"  D=0
ISEL   I   "Option flag"  D=11
SIZE   R   "Character size (cm) for particle names"  D=0.25
```

```
CALL GDPART(itra,isel,size)
isel=x1 to draw the track number
isel=1x to draw the particle name
```

3.30   DHITS [chuset chudet itra isymb ssymb]

```
CHUSET   C   "User set identifier"  D='*'
CHUDET   C   "User detector identifier"  D='*'
ITRA     I   "Number of the selected track"  D=0
ISYMB    I   "Character selection number"  D=0
SSYMB    R   "Size of characters (cm)"  D=0.1
```

CALL GDHITS(chuset,chudet,itra,isymb,ssymb). The character plotted at each hit point may be chosen by isymb :

```
   -1   (small) hardware points              (fast)
    0   software crosses                     (default)
840,850   empty/full circles                  (slow)
841,851   empty/full squares                  (slow)
842,852   empty/full triangles (up)           (slow)
843,853   empty diamond/full triangle (down)  (slow)
844,854   empty/full stars                    (slow)
```

Except for isymb=-1, the size of the character on the screen can be chosen by SSYMB cm. The hit colour will follow the value of TXCI (text colour) for isymb⟩0, the value of PMCI (polymarkers colour) for isymb⟨0, the value of PLCI (polyline colour) for isymb=0.

3.31   KHITS [chuset chudet epsilo]

```
CHUSET   C   "User set identifier"  D='*'
CHUDET   C   "User detector identifier"  D='*'
EPSILO   R   "Pick aperture"  D=0.1
```

```
CALL GKHITS(chuset,chudet,epsilo)
```

The picking of hit points requires the appropriate JSET data structure have been filled and is repeated until the character typed is 'Q' or 'q' (GKS) or the right button of the mouse is clicked (X11). If the character typed to pick is 'K' or 'k' then the kinematics of the corresponding track is also printed. The search is made of all the hits of all tracks in detector CHUDET of set CHUSET. EPSILO is the pick aperture; if EPSILO⟨0 its absolute value is taken and in addition the pick aperture is drawn; if EPSILO=0 there is an infinite pick aperture and over all the hits the one nearest to the pick point is taken.

3.32   DCHIT [chuset chudet itra isymb sizmax ihit hitmin hitmax]

```
CHUSET   C   "User set identifier"  D='*'
CHUDET   C   "User detector identifier"  D='*'
ITRA     I   "Number of the selected track"  D=0
ISYMB    I   "Character selection number"  D=0
SIZMAX   R   "Maximum character size (cm)"  D=1
IHIT     I   "Index of array HITS"  D=4
HITMIN   R   "Lower boundary of HITS(IHIT)"  D=0
HITMAX   R   "Upper boundary of HITS(IHIT)"  D=0
```

```
CALL GDCHIT(chuset,chudet,itra,isymb,sizmax,ihit,hitmin,hitmax)
```

The character plotted at each hit point may be chosen via CSYMB; isymb is composed as:

```
     -1    (small) hardware points              (fast)
      0    software crosses                     (default)
840,850    empty/full circles                   (slow)
841,851    empty/full squares                   (slow)
842,852    empty/full triangles (up)            (slow)
843,853    empty diamond/full triangle (down)  (slow)
844,854    empty/full stars                     (slow)
```

Except for isymb=-1 the SIZE of the character on the screen is a function of HITS(IHIT), the array containing the calorimeter quantity, with HITMIN and HITMAX defining its range. The maximum character size (used in overflow) is SIZMAX.

```
SIZE = SIZMAX * ( HITS(IHIT) - HITMIN ) / HITMAX
```

3.33   DUVIEW name type cpxtyp [iview]

```
NAME     C   "Detector name"
TYPE     C   "View name"
CPXTYP   C   "Complexity name"
IVIEW    I   "View number where picture is stored"  D=0
```

```
CALL GUVIEW(name,type,cpxtyp,iview)
```

4   GEANT/GRAPHICS_CONTROL

Graphics control commands.

4.1   DOPEN iview

```
IVIEW   I   "View number"
```

```
CALL GDOPEN(iview)
```

When a drawing is very complex and requires a long time to be executed, it can be useful to store it in a view bank: after a call to DOPEN and the execution of the drawing (nothing will appear on the screen), and after a necessary call to DCLOSE, the contents of the bank can be displayed in a very fast way through a call to DSHOW; therefore, the detector can be easily zoomed many times in different ways. Please note that the pictures with solid colours can now be stored in a view bank or in 'PICTURE FILES'.

4.2   DSHOW [iview]

```
IVIEW   I   "View number"
```

```
CALL GDSHOW(iview)
```

It shows on the screen the contents of a view bank. It can be called after a view bank has been closed.

4.3   DELETE iview

```
IVIEW   I   "View number"
```

```
CALL GDELET(iview)
```

It deletes a view bank from memory.

4.4   DCLOSE

```
CALL GDCLOS
```

It closes the currently open view bank; it must be called after the end of the drawing to be stored.

4.5   CHANGEWK

CALL GCHNWK It open a new workstation (if not already opened) and activate it (deactivating the default one).

4.6   RESETWK

CALL GRESWK It deactivate the previosly activated workstation and reactivate the default one.

4.7   SSETAT iopt

```
IOPT   C   "Attribute name"
```

Set current attribute.

4.8 SSETVA [rval]

```
RVAL   R   "Attribute value"  D=1.   R=-10.:10.
```

Set current attribute value.

4.9 SATT [name iopt ival]

```
NAME   C   "Volume name"  D='* '
IOPT   C   "Name of the attribute to be set"  D='DEFA'
IVAL   I   "Value to which the attribute is to be set"  D=10000
```

```
CALL GSATT(name,iopt,ival)
```

name='*' stands for all the volumes. iopt can be chosen among the following :

```
'WORK'   0=volume name is inactive for the tracking
         1=volume name is active for the tracking (default)
'SEEN'   0=volume name is invisible
         1=volume name is visible (default)
        -1=volume invisible with all its descendants in the tree
        -2=volume visible but not its descendants in the tree
'LSTY'   line style 1,2,3,... (default=1)
         LSTY=7 will produce a very precise approximation for
         revolution bodies.
'LWID'   line width -7,...,1,2,3,..7 (default=1)
         LWID<0 will act as abs(LWID) was set for the volume
         and for all the levels below it. When SHAD is 'ON', LWID
         represent the linewidth of the scan lines filling the surfaces
         (whereas the FILL value represent their number). Therefore
         tuning this parameter will help to obtain the desired
         quality/performance ratio.
'COLO'   colour code -166,...,1,2,..166 (default=1)
         n=1=black
         n=2=red;    n=17+m, m=0,25, increasing luminosity according to
'm';
         n=3=green;  n=67+m, m=0,25, increasing luminosity according to
'm';
         n=4=blue;   n=117+m, m=0,25, increasing luminosity according to
'm';
         n=5=yellow; n=42+m, m=0,25, increasing luminosity according to
'm';
         n=6=violet; n=142+m, m=0,25, increasing luminosity according to
'm';
         n=7=lightblue; n=92+m, m=0,25, increasing luminosity according to
'm';
         colour=n*10+m, m=1,2,...9, will produce the same colour
         as 'n', but with increasing luminosity according to 'm';
         COLO<0 will act as if abs(COLO) was set for the volume
```

and for all the levels below it.
                  When for a volume the attribute FILL is > 1 (and the
                  option SHAD is on), the ABS of its colour code must be < 8
                  because an automatic shading of its faces will be
                  performed.
    'FILL'   (1992) fill area -7,...,0,1,...7 (default=0)
                  when option SHAD is 'on' the FILL attribute of any
                  volume can be set different from 0 (normal drawing);
                  if it is set to 1, the faces of such volume will be filled
                  with solid colours; if ABS(FILL) is > 1, then a light
                  source is placed along the observer line, and the faces of
                  such volumes will be painted by colours whose luminosity
                  will depend on the amount of light reflected;
                  if ABS(FILL) = 1, then it is possible to use all the 166
                  colours of the colour table, becouse the automatic shading
                  is not performed;
                  for increasing values of FILL the drawing will be performed
                  with higher and higher resolution improving the quality (the
                  number of scan lines used to fill the faces increases with FILL);
                  it is possible to set different values of FILL
                  for different volumes, in order to optimize at the same time
                  the performance and the quality of the picture;
                  FILL<0 will act as if abs(FILL) was set for the volume
                  and for all the levels below it.
                  This kind of drawing can be saved in 'picture files'
                  or in view banks.
                  0=drawing without fill area
                  1=faces filled with solid colours and resolution = 6
                  2=lowest resolution (very fast)
                  3=default resolution
                  4=................
                  5=................
                  6=................
                  7=max resolution
                  Finally, if a coloured background is desired, the FILL
                  attribute for the first volume of the tree must be set
                  equal to -abs(colo), colo being >0 and <166.
    'SET '   set number associated to volume name
    'DET '   detector number associated to volume name
    'DTYP'   detector type (1,2)

4.10 SCALE gscu gscv

      GSCU   R   "Scale factor for U-coord."
      GSCV   R   "Scale factor for V-coord."

Change the scale factors GSCU and GSCV in /GCDRAW/.

4.11 COLOR icol

      ICOL   I   "Colour code" D=1

```
         CALL GDCOL(-abs(icol))
```

4.12   LWID lwidth

```
   LWIDTH   I   "Line width code"  D=1
```

```
   CALL GDLW(-abs(lwidth))
```

4.13   NEXT

Clear screen (start a new picture on graphics file, if opened).

4.14   DOPT [iopt ival]

```
   IOPT   C   "Option name"  D='*'
   IVAL   C   "Option value"  D='*'
```

```
   CALL GDOPT(iopt,ival)
```

To set/modify the drawing options.

```
   IOPT   IVAL       Action
   THRZ    ON        Draw tracks in R vs Z
           OFF (D)   Draw tracks in X,Y,Z
           180
           360
   PROJ    PARA (D)  Parallel projection
           PERS      Perspective
   TRAK    LINE (D)  Trajectory drawn with lines
           POIN         " " with markers
   HIDE    ON        Hidden line removal using the CG package
           OFF (D)   No hidden line removal
   SHAD    ON        Fill area and shading of surfaces.
           OFF (D)   Normal hidden line removal.
   RAYT    ON        Ray-tracing on.
           OFF (D)   Ray-tracing off.
   EDGE    OFF       Does not draw contours when shad is on.
           ON  (D)   Normal shading.
   MAPP    1,2,3,4   Mapping before ray-tracing.
           0   (D)   No mapping.
   USER    ON        User graphics options in the raytracing.
           OFF (D)   Automatic graphics options.
```

4.15   SIZE [xsize ysize]

```
   XSIZE   R   "Size along X"  D=20.
   YSIZE   R   "Size along Y"  D=20.
```

Set the size of the picture. On the terminal, the pictures will have the ratio YSIZE/XSIZE, and, if a metafile is produced, pictures will be YSIZE by XSIZE cm. This command sets the parameters for the normalisation transformation number 1 to [0-XSIZE], [0-YSIZE].

4.16   SPERS dpers

```
DPERS   R   "Distance from the origin"
```

Set the variable dpers in /GCDRAW/, representing the distance from the origin when using option PER-Spective.

4.17   MAP_COLOR [icadd icval]

```
ICADD   I   "Colour table index"  D=0
ICVAL   I   "Colour table value"  D=0
```

Sets the color table LOOKTB(ICADD)=ICVAL. If ICADD=0 then LOOKTB(1:16) is taken. If ICVAL is omitted the current value of LOOKTB(ICADD) is shown.

5 GEANT/GEOMETRY

Geometry commands.

5.1 OPTI iopti

```
IOPTI   C   "GSORD optimisation level"  D='0' Minus
```

Possible `IOPTI` values are:

```
-1

 2
```

This flag controls the tracking optimisation performed via the GSORD routine:

```
1 no optimisation at all; GSORD calls disabled;
0 no optimisation; only user calls to GSORD kept;
1 all non-GSORDered volumes are ordered along the best axis;
2 all volumes are ordered along the best axis.
```

5.2 SVOLU name shape numed npar par

```
NAME    C   "Volume name"
SHAPE   C   "Volume type"
NUMED   I   "Tracking medium number"
NPAR    I   "Number of shape parameters"
PAR     C   "Vector containing shape parameters"
```

```
CALL GSVOLU(name,shape,numed,par,npar,ivolu)
```

where par is a KUIP vector. It creates a new volume in the JVOLUM data structure.

5.3 SPOS name number mother x0 y0 z0 irot only

```
NAME     C   "Volume name"
NUMBER   I   "Copy number of the volume"
MOTHER   C   "Mother volume name"
X0       R   "X coord. of the volume in mother ref. sys."
Y0       R   "Y coord. of the volume in mother ref. sys."
Z0       R   "Z coord. of the volume in mother ref. sys."
IROT     I   "Rotation matrix number w.r.t. mother ref. sys."
ONLY     C   "ONLY/MANY flag"
```

```
CALL GSPOS(name,number,mother,x0,y0,z0,irot,only)
```

It positions a previously defined volume in the mother.

5.4 SDVN name mother ndiv caxis

```
NAME     C   "Volume name"
```

```
MOTHER   C   "Mother volume name"
NDIV     I   "Number of divisions"
CAXIS    C   "Axis value"
```

Possible `CAXIS` values are:

```
 X

 Y

 Z

 1

 2

 3
```

```
    CALL GSDVN(name,mother,ndiv,iaxis)
```

X,Y,Z of CAXIS will be translated to 1,2,3 for IAXIS. It divides a previously defined volume.

5.5   PVOLU numb

```
   NUMB   I   "Volume ID"
```

```
   CALL GPVOLU(numb)
```

Prints volumes' specifications.

5.6   SROTM irot theta1 phi1 theta2 phi2 theta3 phi3

```
   IROT      I   "Rotation matrix number"
   THETA1    R   "Polar angle for axis I"    D=0.   R=0.:180.
   PHI1      R   "Azimuthal angle for axis I"   D=0.   R=0.:360.
   THETA2    R   "Polar angle for axis II"   D=0.   R=0.:180.
   PHI2      R   "Azimuthal angle for axis II"  D=0.   R=0.:360.
   THETA3    R   "Polar angle for axis III"  D=0.   R=0.:180.
   PHI3      R   "Azimuthal angle for axis III" D=0.   R=0.:360.
```

```
   CALL GSROTM(irot,theta1,phi1,theta2,phi2,theta3,phi3)
```

It defines the rotation matrix number IROT.

5.7   PROTM numb

```
   NUMB   I   "Matrix ID"
```

```
   CALL GPROTM(numb)
```

Print matrixes' specifications.

5.8   STMED ntmed name nmat isvol ifield fieldm tmaxfd stemax deemax epsil stmin

```
NTMED    I   "Tracking medium number"  D=1
NAME     C   "Tracking medium name"
NMAT     I   "Material number"  D=1
ISVOL    I   "Sensitive volume flag"  D=0
IFIELD   I   "Magnetic field"  D=0
FIELDM   R   "Max. field value (Kilogauss)"  D=0
TMAXFD   R   "Max. angle due to field (deg/step)"  D=0.01
STEMAX   R   "Max. step allowed"  D=1.E+10
DEEMAX   R   "Max. fraction of energy lost in a step"  D=0.01
EPSIL    R   "Tracking precision (cm)"  D=0.01
STMIN    R   "Min. step due to continuos processes (cm)"  D=0.1
```

```
      CALL GSTMED(ntmed,name,nmat,isvol,ifield,fieldm,tmaxfd,
     +            stemax,deemax,epsil,stmin,0,0)
```

IFIELD = 0 if no magnetic field; IFIELD = -1 if user decision in GUSWIM; IFIELD = 1 if tracking performed with GRKUTA; IFIELD = 2 if tracking performed with GHELIX; IFIELD = 3 if tracking performed with GHELX3.

5.9   PTMED numb

```
  NUMB   I   "Medium ID"
```

```
CALL GPTMED(numb)
```

Print tracking media's specifications.

5.10   EDITV [isel name]

```
  ISEL   I   "Options"  D=0
  NAME   C   "Volume name"  D=' '
```

```
CALL GEDITV(isel,name)
```

When the routine prompts for input parameters that do not need to be changed, type return. ISEL is used to select the editing operation to be performed:

```
ISEL=0, CALL GGCLOS
ISEL=1, to modify shape parameters PAR given by GSVOLU
ISEL=2, to modify NAME given by GSVOLU
ISEL=3, to delete NAME given by GSVOLU
ISEL=4, to unlink NAME,NR given by GSPOS/GSDVN/GSDV..
ISEL=5, to modify X0,Y0,Z0 of NAME,NR given by GSPOS
ISEL=6, to modify IROT of NAME,NR given by GSPOS
ISEL=7, to modify NDIV given by GSDVN
ISEL=8, to modify IAXIS given by GSDVN
```

5.11   CADINT fname aname nbins lunit lunit2 inst site dept resp

```
FNAME    C   "Name of the SET file"  D='example.set'
ANAME    C   "Name of the volume"
NBINS    I   "Number of the instances"  D=1
LUNIT    I   "Logical unit number for SET file"  D=66
LUNIT2   I   "Logical unit number for material file"  D=67
INST     C   "Name of your institute"  D='CERN'
SITE     C   "Name of site"  D='MEYRIN'
DEPT     C   "Name of departement"  D='CN'
RESP     C   "Name of sender"  D='god_knows_who'

  CALL GTXSET(fname,aname,nbins,lunit,lunit2,inst,site,dept,resp)
```

This command produces a SET file describing the given volume with the contents currently set visible. (Use the visibility attribute, see SATT SEEN.) The description is given as a flat assembly related to the global coordinate system. The ouput can be read into CAD systems (EUCLID-IS) trough a SET interface. A list of materials of the volumes in the SET file and the GEANT tree is written into a file with the same filename as the SET file, but with extension .mat.

5.12 REUCLID lun fname

```
LUN     I   "Logical unit of the file to be read"  R=1:100
FNAME   C   "Name of the EUCLID file to be read"

  CALL GREUCL(LUN,FNAME)
```

Calls the routine to read into GEANT a geometry from an ASCII file written by the EUCLID-GEANT interface.

5.13 WEUCLID lun fname topvol [number nlevel]

```
LUN      I   "Logical unit of the file to be written"  R=1:100
FNAME    C   "Name of the EUCLID file to be written"
TOPVOL   C   "Volume name of the starting node"
NUMBER   I   "Copy number of TOPVOL (relevant for GSPOSP)"  D=1
NLEVEL   I   "Number of levels in the tree structure"  D=15

  CALL GWEUCL(LUN,FNAME)
```

Calls the routine to write the current GEANT geometry into an ASCII file in EUCLID compatible format.

6   GEANT/CREATE

It creates volumes of the given shape interactively.   CALL GSVOLU(name,shape,numed,par,npar,ivolu)
where par is a KUIP vector

6.1   SBOX name numed halfx halfy halfz [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`HALFX`	R	"Half X length"
`HALFY`	R	"Half Y length"
`HALFZ`	R	"Half Z length"
`YESNO`	C	"GSPOSP option" `D='NO'`

Possible `YESNO` values are:
 `YES`

 `NO`

6.2   STRD1 name numed hlfdwx hlfupx halfy halfz [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`HLFDWX`	R	"Half X length in Lower Z Surface"
`HLFUPX`	R	"Half X length in Upper Z Surface"
`HALFY`	R	"Half Y length"
`HALFZ`	R	"Half Z length"
`YESNO`	C	"GSPOSP option" `D='NO'`

Possible `YESNO` values are:
 `YES`

 `NO`

6.3   STRD2 name numed hlfdwx hlfupx hlfdwy hlfupy halfz [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`HLFDWX`	R	"Half X length in Lower Z Surface"
`HLFUPX`	R	"Half X length in Upper Z Surface"
`HLFDWY`	R	"Half Y length in Lower Z Surface"
`HLFUPY`	R	"Half Y length in Upper Z Surface"
`HALFZ`	R	"Half Z length"
`YESNO`	C	"GSPOSP option" `D='NO'`

Possible `YESNO` values are:

```
YES

NO
```

6.4   STUBE name numed inrad outrad halfz [yesno]

```
NAME     C   "Volume name"
NUMED    I   "Tracking medium number"
INRAD    R   "Inside Radius"
OUTRAD   R   "Outside Radius"
HALFZ    R   "Half Z length"
YESNO    C   "GSPOSP option"  D='NO'
```

Possible `YESNO` values are:
```
YES

NO
```

6.5   STUBS name numed inrad outrad halfz sphi ephi [yesno]

```
NAME     C   "Volume name"
NUMED    I   "Tracking medium number"
INRAD    R   "Inside Radius"
OUTRAD   R   "Outside Radius"
HALFZ    R   "Half Z length"
SPHI     R   "Start of section PHI"  R=0.:360.
EPHI     R   "End of section PHI"  R=0.:360.
YESNO    C   "GSPOSP option"  D='NO'
```

Possible `YESNO` values are:
```
YES

NO
```

6.6   SCONE name numed inrdw outrdw inrup outrup halfz [yesno]

```
NAME     C   "Volume name"
NUMED    I   "Tracking medium number"
INRDW    R   "Inside Radius in Lower Z Surface"
OUTRDW   R   "Outside Radius in Lower Z Surface"
INRUP    R   "Inside Radius in Upper Z Surface"
OUTRUP   R   "Outside Radius in Upper Z Surface"
HALFZ    R   "Half Z length"
YESNO    C   "GSPOSP option"  D='NO'
```

Possible `YESNO` values are:

```
YES

NO
```

6.7   SCONS name numed inrdw outrdw inrup outrup halfz sphi ephi [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`INRDW`	R	"Inside Radius in Lower Z Surface"
`OUTRDW`	R	"Outside Radius in Lower Z Surface"
`INRUP`	R	"Inside Radius in Upper Z Surface"
`OUTRUP`	R	"Outside Radius in Upper Z Surface"
`HALFZ`	R	"Half Z length"
`SPHI`	R	"Start of section PHI" `R=0.:360.`
`EPHI`	R	"End of section PHI" `R=0.:360.`
`YESNO`	C	"GSPOSP option" `D='NO'`

Possible `YESNO` values are:
```
YES

NO
```

6.8   SSPHE name numed inrad outrad sphi ephi stheta etheta [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`INRAD`	R	"Inside Radius"
`OUTRAD`	R	"Outside Radius"
`SPHI`	R	"Start of section PHI" `R=0.:360.`
`EPHI`	R	"End of section PHI" `R=0.:360.`
`STHETA`	R	"Start of section THETA"
`ETHETA`	R	"End of section THETA"
`YESNO`	C	"GSPOSP option" `D='NO'`

Possible `YESNO` values are:
```
YES

NO
```

6.9   SPARA name numed halfx halfy halfz axis phi theta [yesno]

`NAME`	C	"Volume name"
`NUMED`	I	"Tracking medium number"
`HALFX`	R	"Half X length"
`HALFY`	R	"Half Y length"
`HALFZ`	R	"Half Z length"
`AXIS`	R	"Angle of Y mid-faces segment to Y axis" `R=0.:360.`
`PHI`	R	"PHI angle of Low Z mid-face to High Z mid-face segment" `R=0.:360.`

THETA R "THETA angle of mid-low-Z-face to mid-high-Z-face segment" R=0.:360.

YESNO C "GSPOSP option" D='NO'

Possible YESNO values are:

YES

NO

7 GEANT/CONTROL

Control commands.

7.1 KINE ikine [pkine1 pkine2 pkine3 pkine4 pkine5 pkine6 pkine7 pkine8 pkine9 pkine10]

```
IKINE     I   "IKINE"  D=1
PKINE1    R   "PKINE(1)"
PKINE2    R   "PKINE(2)"
PKINE3    R   "PKINE(3)"
PKINE4    R   "PKINE(4)"
PKINE5    R   "PKINE(5)"
PKINE6    R   "PKINE(6)"
PKINE7    R   "PKINE(7)"
PKINE8    R   "PKINE(8)"
PKINE9    R   "PKINE(9)"
PKINE10   R   "PKINE(10)"
```

Set the variables in /GCFLAG/ IKINE, PKINE(10)

7.2 RUNG idrun idevt

```
IDRUN   I   "User run number"
IDEVT   I   "User starting event number"
```

Set the run number and the starting value for the user event number.

7.3 SORD istord

```
ISTORD   C   "Flag to control user ordering of the stack"  D='1'
```

Possible ISTORD values are:

```
 1

 0
```

If ISTORD is set to 1, the particle with the highest value of the user weight UPWGHT will be selected to be tracked next.

7.4 GTIME timint timend itime

```
TIMINT   R   "Total time after initialisation"
TIMEND   R   "Time reserved for the termination phase"
ITIME    I   "Frequency of control printing"
```

These commands have limited use in the interactive version. In particular the value of TIMINT is disregarded by GEANT.

7.5 TRACK

Restart tracking, clearing the track and hit banks, but keeping the kinematics.

7.6 TRIGGER [n]

```
N   I   "Number of events"  D=1
```

Start one or more new events.

7.7 RNDM [iseed1 iseed2]

```
ISEED1   I   "First seed for the random number generator"
ISEED2   I   "Second seed for the random number generator"
```

Set the seeds for the random number generator. If no numbers are given, the currents seeds are printed.

7.8 SWITCH iswi ival

```
ISWI   I   "Switch number"
IVAL   I   "New switch value"
```

Change one element of array ISWIT(10) in /GCFLAG/

7.9 MZLOGL level

```
LEVEL   I   "MZ log level"  D=0
```

Set the log level for the MZ package of ZEBRA: CALL MZLOGL(0,level)

```
LEVEL = -3   no messages at all
        -2   error messages only
        -1   terse logging
         0   normal
        +1   log rare events
        +2   log calls to MZ routines
```

7.10 PRINT name number

```
NAME     C   "Name"
NUMBER   I   "Number"  D=0
```

```
CALL GPRINT(name,number)
```

7.11 OUTPUT_LP lout

```
LOUT   I   "New output unit"
```

To change lout in /GCUNIT/ Note: unit numbers 5,11,12,13,14,15 are reserved and cannot be used.

7.12 PHITS [chuset chudet numhi]

```
CHUSET   C   "User set"  D='*'
CHUDET   C   "User detector"  D='*'
NUMHI    I   "Hit number"  D=0
```

```
CALL GPHITS(chuset,chudet)
```

7.13 PDIGI [chuset chudet]

```
CHUSET   C   "User set"  D='*'
CHUDET   C   "User detector"  D='*'
```

```
CALL GPDIGI(chuset,chudet)
```

7.14 SMATE imat namate a z dens radl absl ubuf nwbuf

```
IMAT     I   "Material number"
NAMATE   C   "Material name"
A        R   "Atomic weight"
Z        R   "Atomic number"
DENS     R   "Density"
RADL     R   "Radiation lenght"
ABSL     R   "Absorption lenght"
UBUF     R   " "
NWBUF    I   " "
```

```
CALL GSMATE(imat,namate,a,z,dens,radl,absl,ubuf,nwbuf)
```

7.15 SMIXT imat namate a z dens nlmat wmat

```
IMAT     I   "Material number"
NAMATE   C   "Material name"
A        R   "Atomic weight"
Z        R   "Atomic number"
DENS     R   "Density"
NLMAT    I   "Flag for WMAT"
WMAT     R   "Relative weights or n. of atoms in molecule"
```

```
CALL GSMIXT(imat,namate,a,z,dens,nlmat,wmat)
```

7.16 PMATE numb

```
NUMB   I   "Material number"
```

```
CALL GPMATE(numb)
```

7.17 PRMAT imate ipart mecan

```
IMATE   I   "Material number"
IPART   I   "Particle number"
MECAN   C   "Mechanism"
```

```
CALL GPRMAT(imate,ipart,mecan,nekbin,elow)
```

7.18 PLMAT imate ipart mecan [idm]

```
IMATE   I   "Material number"
IPART   I   "Particle number"
MECAN   C   "Mechanism"
IDM     I   "ID mode option"  D=0
```

CALL GPLMAT(imate,ipart,mecan,nekbin,elow,idm)

```
IDM convention for histogramming mode :
IDM.gt.0  fill, print,   keep   histogram(s)
IDM.eq.0  fill, print,   delete histogram(s)
IDM.lt.0  fill, noprint, keep   histogram(s)
```

If MECAN = 'ALL' all the mechanisms are histogrammed. If the material number is negative, the cross sections relative to material ABS(IMATE) will be histogrammed in barns rather than in 1/cm.

7.19 DRMAT imate ipart [mecan]

```
IMATE   I   "Material number"
IPART   I   "Particle number"
MECAN   C   "List of mechanism"  D='ALL'
```

CALL GDRMAT(imate,ipart,mecan,nmec) If MECAN = 'ALL' all the mechanisms are plotted. If the material number is negative, the cross sections relative to material ABS(IMATE) will be plotted in barns rather than in 1/cm. Note that it is not possible to plot anything if GSTMED has not been called for the material number IMATE.

7.20 STPAR itmed chpar parval

```
ITMED    I   "Medium number"
CHPAR    C   "Cut or mechanism"
PARVAL   R   "Value"
```

CALL GSTPAR(itmed,chpar,parval)

7.21 SPART ipart napart itrtyp amass charge tlife ubuf nwbuf bratio mode

```
IPART    I   "Particle number"
NAPART   C   "Particle name"
```

```
ITRTYP    I    " "
AMASS     R    "Mass"
CHARGE    R    "Charge"
TLIFE     R    "Lifetime"
UBUF      R    " "
NWBUF     I    " "
BRATIO    R    "Branching ratios"
MODE      I    "Decay mode"
```

CALL GSPART(ipart,napart,itrtyp,amass,charge,tlife,ubuf,nwbuf); CALL GSDK(ipart,bratio,mode)

7.22   PPART numb

```
NUMB    I    "Particle number"
```

CALL GPPART(numb)

7.23   PRKINE numb

```
NUMB    I    "Track number"
```

CALL GPKINE(numb)

7.24   DEBUG [ideb]

```
IDEB    C    "Debug option"  D='ON'
```

Possible `IDEB` values are:
 `ON`
 `OFF`
If ideb='ON ' then :

```
idebug=1, idemin=1, idemax=1000000, itime=1
```

else :

```
idebug=0, idemin=0, idemax=0
```

8   GEANT/RZ

ZEBRA/RZ commands.

8.1   PQUEST [iq1 iq2]

```
IQ1   I   "Lower limit for IQ index"  D=1
IQ2   I   "Upper limit for IQ index"  D=20
```

Print the array IQUEST in /QUEST/.

8.2   FILE lun fname [chopt]

```
LUN     I   "Logical unit number"
FNAME   C   "File name"
CHOPT   C   "Options"  D='␣'
```

Possible `CHOPT` values are:

```
'␣'
```

```
A
```

```
N
```

```
U
```

Open a GRZ file.

```
CHOPT=' ' readonly mode
CHOPT='U' update mode
CHOPT='N' create new file
CHOPT='I' Read all structures from existing file
CHOPT='O' Write all structures on file
```

8.3   REND lunrz

```
LUNRZ   I   "Logical unit number"
```

Close an RZ file opened by GRFILE on logical unit LUNRZ.

```
CALL GREND(LUNRZ)
```

8.4   MDIR chdir [chopt]

```
CHDIR   C   "Directory name"
CHOPT   C   "Options"  D='␣'
```

To create a new RZ directory below the current directory. with

```
RZTAGS(1)='Object'
RZTAGS(2)='Idvers-NR '
```

8.5 CDIR [chpath chopt]

```
CHPATH   C   "Path name"  D='␣'
CHOPT    C   "CHOPT"  D='␣'
```

Change or print the current directory.

```
Ex.  CD dir1          ; make DIR1 the new CWD
     CD //file1/dir2 ; make //FILE1/DIR2 the new CWD
     CD               ; print the name of the CWD
```

8.6 IN object [idvers chopt]

```
OBJECT   C   "Structure name"
IDVERS   I   "Version number"  D=1
CHOPT    C   "Option"  D='␣'
```

Read data structure identified by OBJECT,IDVERS into memory.

```
MATE read JMATE structure
TMED read JTMED structure
VOLU read JVOLUM structure
ROTM read JROTM structure
SETS read JSET  structure
PART read JPART structure
SCAN read LSCAN structure
INIT read all above data structures
```

8.7 OUT object [idvers chopt]

```
OBJECT   C   "Structure name"
IDVERS   I   "Version number"  D=1
CHOPT    C   "Option"  D='␣'
```

Write data structure identified by OBJECT,IDVERS to RZ file.

```
MATE write JMATE structure
TMED write JTMED structure
VOLU write JVOLUM structure
ROTM write JROTM structure
SETS write JSET  structure
PART write JPART structure
SCAN write LSCAN structure
INIT write all above data structures
```

8.8 LDIR [chpath chopt]

```
CHPATH   C   "Path name"  D='␣'
CHOPT    C   "CHOPT"  D='␣'
```

List the contents of a directory (memory or disk). To list all RZ files currently open, type 'LD //'.

8.9   PURGE [nkeep]

```
 NKEEP   I   "Number of cycles to keep"  D=1
```

Purge an RZ directory.

8.10   SCR object [idvers]

```
 OBJECT   C   "Structure name"
 IDVERS   I   "Version number"  D=1
```

Delete entry identified by OBJECT,IDVERS on RZ file. OBJECT may be : MATE,TMED,VOLU,ROTM,SETS,PART,SCAN,
* If OBJECT= * delete all entries with IDVERS.

8.11   LOCK chdir

```
 CHDIR   C   "Lock identifier"  D='RZFILE'
```

Lock an RZ directory.

8.12   FREE chdir

```
 CHDIR   C   "Lock identifier"  D='RZFILE'
```

Free an RZ directory.

9 GEANT/FZ

ZEBRA/FZ commands

9.1 FZIN lun keysu [ident]

```
LUN     I   "Fortran unit of the FZ file"
KEYSU   C   "Name of the data structure to be retrieved"
IDENT   I   "Version of the data structure to be retrieved"  D=0
```

Equivalent to a call to:

```
CALL GFIN(LUN,KEYSU,1,IDENT,' ',IER)
```

9.2 FZOPEN lun file luntyp len [chopt]

```
LUN      I   "Fortran unit with which to open the file"
FILE     C   "Name of the file to be opened"
LUNTYP   C   "Type of FZ file to be opened by GOPEN"  D='XI'
LEN      I   "Recordlenght of the file"  D=0
CHOPT    C   "Optional parameter to specify the action"  D='␣'
```

Equivalent to a call to:

```
CALL GOPEN(LUN,FILE,LUNTYP,LEN,IER)
```

If CHOPT = I then a call to GFIN or GFOUT will be performed in addition according to the value of LUNTYP, with the key INIT to save or retrieve the whole initialization data structure.

9.3 FZOUT lun keysu [ident]

```
LUN     I   "Fortran unit of the FZ file"
KEYSU   C   "Name of the data structure to be saved"
IDENT   I   "Version of the data structure to be saved"  D=1
```

Equivalent to a call to:

```
CALL GFOUT(LUN,KEYSU,1,IDENT,' ',IER)
```

9.4 FZCLOSE lun

```
LUN   I   "Fortran unit of the FZ to close"
```

Equivalent to a call to:

```
CALL GCLOSE(LUN,IER)
```

10   GEANT/DZ

10.1   SURV name [number]

```
NAME     C   "Bank name"
NUMBER   I   "Bank number"  D=1
```

Print a survey of the structure identified by NAME, NUMBER.

10.2   SHOW name [number chopt]

```
NAME     C   "Bank name"
NUMBER   I   "Bank number"  D=1
CHOPT    C   "Options"  D='BSV'
```

Display the contents of a bank or a data structure identified by its NAME and NUMBER. The output format of the data part is controlled by the internal or external I/O characteristic.

```
CHOPT='B'  Print the bank.
CHOPT='S'  Print the bank contents from left to right Sideways
           with up to ten elements per line.
CHOPT='V'  Print the vertical (down) structure.
CHOPT='D'  Print the bank contents from top to bottom Downwards
           with five elements per line.
CHOPT='L'  Print the linear structure.
CHOPT='Z'  Print the data part of each bank in hexadecimal format
```

10.3   SNAP [idiv chopt]

```
IDIV    I   "Division number "  D=2 R=0:24
CHOPT   C   "Options"  D='M'
```

Snap of one or more divisions. Provides a snapshot of one or more divisions in a ZEBRA store. The kind of information provided is controlled by CHOPT.

```
CHOPT='M'  Print Map entry for each bank
CHOPT='E'  Extend map entry to dump all links of each bank
           (otherwise only as many links as will fit on a line)
CHOPT='F'  Full. Dump all active banks, links and data
CHOPT='K'  Kill. Dropped banks to be treated as active
           (dropped banks are not normally dumped under D or F option)
CHOPT='L'  Dump all Link areas associated with the store
CHOPT='W'  Dump the Working space, links and data
CHOPT='Z'  Dump the information in hexadecimal.
```

10.4   VERIFY [idiv chopt]

```
IDIV    I   "Division number "  D=0 R=0:24
CHOPT   C   "Options"  D='CLSU'
```

Check the structure of one or more ZEBRA divisions. The verification detail depends on the settings in CHOPT.

```
CHOPT='C' Check chaining of banks only
CHOPT='L' Check validity of the structural links (implies 'C')
CHOPT='S' Check the store parameters
CHOPT='U' Check the validity of the up and origin (implies 'C')
CHOPT='F' Errors are considered fatal and generate a call to ZFATAL
```

10.5   STORE [ixstor]

```
 IXSTOR   I   "Store number"  D=0 R=0:24
```

Display the structure of the ZEBRA store IXSTOR. Output the parameters characterizing the store, followed by a list of all divisions and all link areas associated with the store in question.

10.6   DDIV [idiv path]

```
 IDIV   I   "Division number"  D=2
 PATH   C   "Name of the doc file"  D='␣'
```

Facility to display the layout of stores and divisions.

```
CALL DZDDIV(idiv,LDUMMY,path,'IN',1,0,1,IWTYPE)
```

10.7   DISP bank [path number]

```
 BANK     C   "Name of the bank"
 PATH     C   "Name of the doc file"  D='␣'
 NUMBER   I   "Number of the bank"  D=1
```

Interactive bank display tool.

```
CALL DZDISP(IXSTOR,LBANK,path,'N',1,0,1,IWTYPE)
```

10.8   DIRZ [path]

```
 PATH   C   "Name of the RZ directory to analyse"
```

Facility to display RZ directory trees.

```
CALL DZDIRZ(0,LDUMMY,0,path,'N',1,0,1)
```

11 GEANT/SCAN

To define parameters for the SCAN geometry. If the routine GUSTEP and GUKINE are properly instrumented (see examples in GEANX), when the TRI command is entered NTETA Geantinos will be tracked through the real detector starting at the vertex position defined by the command vertex. A simplified version of the geometry is automatically generated in (ETA,PHI) or (THETA,PHI) following the option given in the command TETA. The data structure LSCAN generated may be saved on an RZ file for subsequent processing. This data structure may be used for fast parametrization techniques.

11.1 PHI nphi [phimin phimax]

```
NPHI     I   "Number of PHI divisions"  D=90
PHIMIN   R   "Minimum PHI in degrees"  D=0.   R=0.:360.
PHIMAX   R   "Maximum PHI in degrees"  D=360.  R=0.:360.
```

To specify number of divisions along PHI. If no parameter is given, the current values of the parameters are displayed.

11.2 TETA nteta [tetmin tetmax divtyp]

```
NTETA    I   "Number of TETA divisions"  D=90
TETMIN   R   "Minimum value of TETA"
TETMAX   R   "Maximum value of TETA"
DIVTYP   I   "Type of TETA division"  R=1:3
```

To specify number of divisions along TETA. If DIVTYP=1 divisions in pseudo-rapidity ETA. If DIVTYP=2 divisions in degrees following the THETA angle. If DIVTYP=3 divisions in cos(TETA). If no parameter is given, the current values of the parameters are displayed.

11.3 SLIST list

```
LIST   C   "List of master volumes"
```

Only boundary crossings of volumes given in LIST will be seen in the SCAN geometry. If no parameters are given, the current SCAN volumes will be listed. If a full stop (.) is given, the list of scan volumes will be erased.

11.4 VERTEX vx vy vz

```
VX   R   "Scan X-origin"  D=0.
VY   R   "Scan Y-origin"  D=0.
VZ   R   "Scan Z-origin"  D=0.
```

All Geantinos tracked will start from position VX,VY,VZ.

11.5 SFACTORS factx0 factl factr

```
FACTX0   R   "Scale factor for SX0"  D=100.
```

```
FACTL    R    "Scale factor for SL"  D=1000.
FACTR    R    "Scale factor for R"  D=100.
```

Set scale factors for SX0,SL and R. The given scale factors must be such that:

```
SX0*FACTX0  <  2**15-1 (32767)
SL*FACTL    <  2**10-1 (1023)
SR*FACTR    <  2**17-1 (131071)
```

11.6   STURN chopt

```
CHOPT   C   "SCAN mode setting"
```

Possible `CHOPT` values are:

`ON`

`OFF`

`INIT`

Switch on/off SCAN mode. If SCAN mode is on, SCAN geantinos are generated and tracked to fill (or complete) the current scan data structure. If SCAN mode is off, normal kinematics generation and tracking will take place. If INIT is given, the current SCAN data structure (if any) will be dropped and SCAN mode will be turned on.

11.7   PCUTS [iparam pcutga pcutel pcutha pcutne pcutmu]

```
IPARAM   I   "Parametrization Flag"  R=0:1
PCUTGA   R   "Parametrization Cut for gammas"
PCUTEL   R   "Parametrization Cut for electrons"
PCUTHA   R   "Parametrization Cut for charged hadrons"
PCUTNE   R   "Parametrization Cut for neutral hadrons"
PCUTMU   R   "Parametrization Cut for muons"
```

Control parametrization at tracking time.

```
IPARAM=0      No parametrization is performed
IPARAM=1      Parametrization is performed
```

If parametrization is active and a particle falls below its parametrization cut, then the particle will be replaced by a parametrized shower which will be tracked in the SCAN geometry.

11.8   LSCAN id [volume chopt]

```
ID       I   "Lego plot identifier"  D=2000
VOLUME   C   "Volume name"  D='XXXX'
CHOPT    C   "List of options"  D='OPX'
```

Possible `CHOPT` values are:

```
’␣’
 O
 P
 I
 X
 L
```

Generates and plot a table of physics quantities such as the total number of radiation lengths or interaction lengths in function of the SCAN parameters TETA,PHI.

```
CHOPT='O' table is generated at Exit  of VOLUME.
CHOPT='I' table is generated at Entry of VOLUME.
CHOPT='X' radiation lengths
CHOPT='L' Interaction lengths
CHOPT='P' Plot the table
```

If VOLUME='XXXX' Mother volume is used.

11.9   HSCAN idphi [volume chopt]

```
IDPHI    I    “Histogram/phi identifier”  D=1000
VOLUME   C    “Volume name”  D='XXXX'
CHOPT    C    “List of options”  D='OPX'
```

Possible CHOPT values are:
```
’␣’
 O
 P
 I
 X
 L
```

Generates and plots an histogram of physics quantities such as the total number of radiation lengths or interaction lengths as a function of the SCAN parameter TETA for a given value of PHI.

```
CHOPT='O' histogram is generated at Exit  of VOLUME.
CHOPT='I' histogram is generated at Entry of VOLUME.
CHOPT='X' radiation lengths
CHOPT='L' Interaction lengths
CHOPT='P' Plot the histogram
```

If VOLUME='XXXX' Mother volume is used. The histogram identifier IDPHI is used to also identify which PHI division to plot: IPHI=MOD(IDPHI,1000). If IPHI=0, then all PHI divisions are generated (not plotted) with histogram identifiers IDPHI+PHI division number.

12   GEANT/PHYSICS

Commands to set physics parameters.

12.1   ANNI [ianni]

```
IANNI   C   "Flag IANNI"  D='1'
```

Possible `IANNI` values are:

```
0

1

2
```

To control positron annihilation.

```
IANNI=0 no annihilation
     =1 annihilation. Decays processed.
     =2 annihilation. No decay products stored.
```

12.2   AUTO [iauto]

```
IAUTO   C   "Flag IAUTO"  D='1'
```

Possible `IAUTO` values are:

```
0

1
```

To control automatic calculation of tracking medium parameters:

```
IAUTO=0 no automatic calculation;
     =1 automati calculation.
```

12.3   BREM [ibrem]

```
IBREM   C   "Flag IBREM"  D='1'
```

Possible `IBREM` values are:

```
0

1

2
```

To control bremstrahlung.

```
IBREM=0 no bremstrahlung
     =1 bremstrahlung. Photon processed.
     =2 bremstrahlung. No photon stored.
```

12.4   CKOV [ickov]

```
ICKOV   C   "Flag ICKOV"  D='0'
```

Possible `ICKOV` values are:

 0

 1

 2

To control Cerenkov production

```
ICOMP=0 no Cerenkov;
      =1 Cerenkov;
      =2 Cerenkov with primary stopped at each step.
```

12.5 COMP [icomp]

```
ICOMP   C   "Flag ICOMP"  D='1'
```

Possible `ICOMP` values are:

 0

 1

 2

To control Compton scattering

```
ICOMP=0 no Compton
      =1 Compton. Electron processed.
      =2 Compton. No electron stored.
```

12.6 DCAY [idcay]

```
IDCAY   C   "Flag IDCAY"  D='1'
```

Possible `IDCAY` values are:

 0

 1

 2

To control Decay mechanism.

```
IDCAY=0 no decays.
      =1 Decays. secondaries processed.
      =2 Decays. No secondaries stored.
```

12.7 DRAY [idray]

```
IDRAY   C   "Flag IDRAY"  D='1'
```

Possible `IDRAY` values are:

```
0

1

2
```

To control delta rays mechanism.

```
IDRAY=0 no delta rays.
     =1 Delta rays. secondaries processed.
     =2 Delta rays. No secondaries stored.
```

12.8   ERAN [ekmin ekmax nekbin]

```
EKMIN    R   "Minimum energy of the tables"  D=1E-5
EKMAX    R   "Maximum energy of the tables"  D=1E+4
NEKBIN   I   "Number of bins in the tables"  D=90 R=1:200
```

To define the range and binning of internal tables.

12.9   HADR [ihadr]

```
IHADR   I   "Flag IHADR"  D=1
```

To control hadronic interactions.

```
IHADR=0 no hadronic interactions.
      =1 Hadronic interactions. secondaries processed.
      =2 Hadronic interactions. No secondaries stored.
```

12.10   LABS [labs]

```
LABS   I   "Flag LABS"  D=0
```

To control absorbtion of Cerenkov photons:

```
LABS=0 no absorbtion of photons;
LABS=1 absorbtion of photons;
```

12.11   LOSS [iloss]

```
ILOSS   C   "Flag ILOSS"  D='2'
```

Possible ILOSS values are:

```
0

1

2

3

4
```

To control energy loss.

```
ILOSS=0 no energy loss;
     =1 restricted energy loss fluctuations;
     =2 complete energy loss fluctuations;
     =3 same as 1;
     =4 no energy loss fluctuations.
```

If the value ILOSS is changed, then cross-sections and energy loss tables must be recomputed via the command 'PHYSI'.

12.12   MULS [imuls]

```
IMULS   C   "Flag IMULS"  D='1'
```

Possible `IMULS` values are:

```
0
```

```
1
```

```
2
```

```
3
```

To control multiple scattering.

```
IMULS=0 no multiple scattering.
     =1 Moliere or Coulomb scattering.
     =2 Moliere or Coulomb scattering.
     =3 Gaussian scattering.
```

12.13   MUNU [imunu]

```
IMUNU   C   "Flag IMUNU"  D='1'
```

Possible `IMUNU` values are:

```
0
```

```
1
```

```
2
```

To control muon nuclear interactions.

```
IMUNU=0 no muon-nuclear interactions.
     =1 Nuclear interactions. Secondaries processed.
     =2 Nuclear interactions. Secondaries not processed.
```

12.14   PAIR [ipair]

```
IPAIR   C   "Flag IPAIR"  D='1'
```

Possible `IPAIR` values are:

```
0

1

2
```

To control pair production mechanism.

```
IPAIR=0 no pair production.
      =1 Pair production. secondaries processed.
      =2 Pair production. No secondaries stored.
```

12.15   PFIS [ipfis]

```
IPFIS   C   "Flag IPFIS"  D='1'
```

Possible `IPFIS` values are:

```
0

1

2
```

To control photo fission mechanism.

```
IPFIS=0 no photo fission.
      =1 Photo fission. secondaries processed.
      =2 Photo fission. No secondaries stored.
```

12.16   PHOT [iphot]

```
IPHOT   C   "Flag IPHOT"  D='1'
```

Possible `IPHOT` values are:

```
0

1

2
```

To control Photo effect.

```
IPHOT=0 no photo electric effect.
      =1 Photo effect. Electron processed.
      =2 Photo effect. No electron stored.
```

12.17   RAYL [irayl]

```
IRAYL   C   "Flag IRAYL"  D='1'
```

Possible `IRAYL` values are:

```
0

1
```

To control Rayleigh scattering.

```
IRAYL=0 no Rayleigh scattering.
     =1 Rayleigh.
```

12.18 STRA [istra]

```
ISTRA   C   "Flag ISTRA"  D='0'
```

Possible `ISTRA` values are:

0

1

2

To control energy loss fluctuation model:

```
ISTRA=0 Urban model;
     =1 PAI model;
     =2 PAI+ASHO model (not active at the moment).
```

12.19 SYNC [isync]

```
ISYNC   C   "Flag ISYNC"  D='1'
```

Possible `ISYNC` values are:

0

1

To control synchrotron radiation:

```
ISYNC=0 no synchrotron radiation;
     =1 synchrotron radiation.
```

12.20 CUTS [cutgam cutele cuthad cutneu cutmuo bcute bcutm dcute dcutm ppcutm tofmax gcuts]

```
CUTGAM  R   "Cut for gammas"  D=0.001
CUTELE  R   "Cut for electrons"  D=0.001
CUTHAD  R   "Cut for charged hadrons"  D=0.01
CUTNEU  R   "Cut for neutral hadrons"  D=0.01
CUTMUO  R   "Cut for muons"  D=0.01
BCUTE   R   "Cut for electron brems."   D=-1.
BCUTM   R   "Cut for muon brems."   D=-1.
DCUTE   R   "Cut for electron delta-rays"  D=-1.
DCUTM   R   "Cut for muon delta-rays"  D=-1.
PPCUTM  R   "Cut for e+e- pairs by muons"  D=0.01
TOFMAX  R   "Time of flight cut"  D=1.E+10
GCUTS   R   "5 user words"  D=0.
```

To change physics cuts. If no parameter is given, the list of the current cuts is printed.

```
If the default values (-1.) for      BCUTE ,BCUTM ,DCUTE ,DCUTM
are not modified, they will be set to CUTGAM,CUTGAM,CUTELE,CUTELE
respectively.
```

If one of the parameters from CUTGAM to PPCUTM included is modified, cross-sections and energy loss tables must be recomputed via the command 'PHYSI'.

12.21   DRPRT ipart imate step [npoint]

```
IPART    I   "GEANT particle number"
IMATE    I   "GEANT material number"
STEP     R   "step length in centimeters"
NPOINT   I   "number of logarithmically spaced energy points"  D=10 R=2:100
```

This routine prints the relevant parameters linked with the energy loss fluctuation.

12.22   PHYSI

Call the GEANT initialisation routine GPHYSI to recompute the tables of cross-sections and energy loss. This command must be invoked after CUTS, LOSS or ERAN commands.

13   GEANT/LISTS

13.1   HSTA [lhsta_1 lhsta_2 lhsta_3 lhsta_4 lhsta_5 lhsta_6 lhsta_7 lhsta_8 lhsta_9 lhsta_10 lhsta_11 lhsta_12 lhsta_13 lhsta_14 lhsta_15 lhsta_16 lhsta_17 lhsta_18 lhsta_19 lhsta_20]

```
LHSTA_1    C   "user word"
LHSTA_2    C   "user word"
LHSTA_3    C   "user word"
LHSTA_4    C   "user word"
LHSTA_5    C   "user word"
LHSTA_6    C   "user word"
LHSTA_7    C   "user word"
LHSTA_8    C   "user word"
LHSTA_9    C   "user word"
LHSTA_10   C   "user word"
LHSTA_11   C   "user word"
LHSTA_12   C   "user word"
LHSTA_13   C   "user word"
LHSTA_14   C   "user word"
LHSTA_15   C   "user word"
LHSTA_16   C   "user word"
LHSTA_17   C   "user word"
LHSTA_18   C   "user word"
LHSTA_19   C   "user word"
LHSTA_20   C   "user word"
```

The command HSTA is similar to the HSTA data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.2   GET [lget_1 lget_2 lget_3 lget_4 lget_5 lget_6 lget_7 lget_8 lget_9 lget_10 lget_11 lget_12 lget_13 lget_14 lget_15 lget_16 lget_17 lget_18 lget_19 lget_20]

```
LGET_1    C   "user word"
LGET_2    C   "user word"
LGET_3    C   "user word"
LGET_4    C   "user word"
LGET_5    C   "user word"
LGET_6    C   "user word"
LGET_7    C   "user word"
LGET_8    C   "user word"
LGET_9    C   "user word"
LGET_10   C   "user word"
LGET_11   C   "user word"
LGET_12   C   "user word"
LGET_13   C   "user word"
LGET_14   C   "user word"
```

```
LGET_15   C   "user word"
LGET_16   C   "user word"
LGET_17   C   "user word"
LGET_18   C   "user word"
LGET_19   C   "user word"
LGET_20   C   "user word"
```

The command GET is similar to the GET data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.3   SAVE [lsave_1 lsave_2 lsave_3 lsave_4 lsave_5 lsave_6 lsave_7 lsave_8 lsave_9 lsave_10 lsave_11 lsave_12 lsave_13 lsave_14 lsave_15 lsave_16 lsave_17 lsave_18 lsave_19 lsave_20]

```
LSAVE_1    C   "user word"
LSAVE_2    C   "user word"
LSAVE_3    C   "user word"
LSAVE_4    C   "user word"
LSAVE_5    C   "user word"
LSAVE_6    C   "user word"
LSAVE_7    C   "user word"
LSAVE_8    C   "user word"
LSAVE_9    C   "user word"
LSAVE_10   C   "user word"
LSAVE_11   C   "user word"
LSAVE_12   C   "user word"
LSAVE_13   C   "user word"
LSAVE_14   C   "user word"
LSAVE_15   C   "user word"
LSAVE_16   C   "user word"
LSAVE_17   C   "user word"
LSAVE_18   C   "user word"
LSAVE_19   C   "user word"
LSAVE_20   C   "user word"
```

The command SAVE is similar to the SAVE data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.4   SETS [lsets_1 lsets_2 lsets_3 lsets_4 lsets_5 lsets_6 lsets_7 lsets_8 lsets_9 lsets_10 lsets_11 lsets_12 lsets_13 lsets_14 lsets_15 lsets_16 lsets_17 lsets_18 lsets_19 lsets_20]

```
LSETS_1    C   "user word"
LSETS_2    C   "user word"
LSETS_3    C   "user word"
LSETS_4    C   "user word"
LSETS_5    C   "user word"
```

```
LSETS_6    C   "user word"
LSETS_7    C   "user word"
LSETS_8    C   "user word"
LSETS_9    C   "user word"
LSETS_10   C   "user word"
LSETS_11   C   "user word"
LSETS_12   C   "user word"
LSETS_13   C   "user word"
LSETS_14   C   "user word"
LSETS_15   C   "user word"
LSETS_16   C   "user word"
LSETS_17   C   "user word"
LSETS_18   C   "user word"
LSETS_19   C   "user word"
LSETS_20   C   "user word"
```

The command SETS is similar to the SETS data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.5   LPRIN [lprin_1 lprin_2 lprin_3 lprin_4 lprin_5 lprin_6 lprin_7 lprin_8 lprin_9 lprin_10 lprin_11 lprin_12 lprin_13 lprin_14 lprin_15 lprin_16 lprin_17 lprin_18 lprin_19 lprin_20]

```
LPRIN_1    C   "user word"
LPRIN_2    C   "user word"
LPRIN_3    C   "user word"
LPRIN_4    C   "user word"
LPRIN_5    C   "user word"
LPRIN_6    C   "user word"
LPRIN_7    C   "user word"
LPRIN_8    C   "user word"
LPRIN_9    C   "user word"
LPRIN_10   C   "user word"
LPRIN_11   C   "user word"
LPRIN_12   C   "user word"
LPRIN_13   C   "user word"
LPRIN_14   C   "user word"
LPRIN_15   C   "user word"
LPRIN_16   C   "user word"
LPRIN_17   C   "user word"
LPRIN_18   C   "user word"
LPRIN_19   C   "user word"
LPRIN_20   C   "user word"
```

The command PRIN is similar to the PRIN data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.6 GEOM [lgeom_1 lgeom_2 lgeom_3 lgeom_4 lgeom_5 lgeom_6 lgeom_7 lgeom_8 lgeom_9 lgeom_10 lgeom_11 lgeom_12 lgeom_13 lgeom_14 lgeom_15 lgeom_16 lgeom_17 lgeom_18 lgeom_19 lgeom_20]

```
LGEOM_1    C    "user word"
LGEOM_2    C    "user word"
LGEOM_3    C    "user word"
LGEOM_4    C    "user word"
LGEOM_5    C    "user word"
LGEOM_6    C    "user word"
LGEOM_7    C    "user word"
LGEOM_8    C    "user word"
LGEOM_9    C    "user word"
LGEOM_10   C    "user word"
LGEOM_11   C    "user word"
LGEOM_12   C    "user word"
LGEOM_13   C    "user word"
LGEOM_14   C    "user word"
LGEOM_15   C    "user word"
LGEOM_16   C    "user word"
LGEOM_17   C    "user word"
LGEOM_18   C    "user word"
LGEOM_19   C    "user word"
LGEOM_20   C    "user word"
```

The command GEOM is similar to the GEOM data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.7 VIEW [lview_1 lview_2 lview_3 lview_4 lview_5 lview_6 lview_7 lview_8 lview_9 lview_10 lview_11 lview_12 lview_13 lview_14 lview_15 lview_16 lview_17 lview_18 lview_19 lview_20]

```
LVIEW_1    C    "user word"
LVIEW_2    C    "user word"
LVIEW_3    C    "user word"
LVIEW_4    C    "user word"
LVIEW_5    C    "user word"
LVIEW_6    C    "user word"
LVIEW_7    C    "user word"
LVIEW_8    C    "user word"
LVIEW_9    C    "user word"
LVIEW_10   C    "user word"
LVIEW_11   C    "user word"
LVIEW_12   C    "user word"
LVIEW_13   C    "user word"
LVIEW_14   C    "user word"
```

```
LVIEW_15   C   "user word"
LVIEW_16   C   "user word"
LVIEW_17   C   "user word"
LVIEW_18   C   "user word"
LVIEW_19   C   "user word"
LVIEW_20   C   "user word"
```

The command VIEW is similar to the VIEW data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.8   PLOT   [lplot_1 lplot_2 lplot_3 lplot_4 lplot_5 lplot_6 lplot_7 lplot_8 lplot_9 lplot_10 lplot_11 lplot_12 lplot_13 lplot_14 lplot_15 lplot_16 lplot_17 lplot_18 lplot_19 lplot_20]

```
LPLOT_1    C   "user word"
LPLOT_2    C   "user word"
LPLOT_3    C   "user word"
LPLOT_4    C   "user word"
LPLOT_5    C   "user word"
LPLOT_6    C   "user word"
LPLOT_7    C   "user word"
LPLOT_8    C   "user word"
LPLOT_9    C   "user word"
LPLOT_10   C   "user word"
LPLOT_11   C   "user word"
LPLOT_12   C   "user word"
LPLOT_13   C   "user word"
LPLOT_14   C   "user word"
LPLOT_15   C   "user word"
LPLOT_16   C   "user word"
LPLOT_17   C   "user word"
LPLOT_18   C   "user word"
LPLOT_19   C   "user word"
LPLOT_20   C   "user word"
```

The command PLOT is similar to the PLOT data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.9   STAT   [lstat_1 lstat_2 lstat_3 lstat_4 lstat_5 lstat_6 lstat_7 lstat_8 lstat_9 lstat_10 lstat_11 lstat_12 lstat_13 lstat_14 lstat_15 lstat_16 lstat_17 lstat_18 lstat_19 lstat_20]

```
LSTAT_1    C   "user word"
LSTAT_2    C   "user word"
LSTAT_3    C   "user word"
LSTAT_4    C   "user word"
LSTAT_5    C   "user word"
LSTAT_6    C   "user word"
```

```
LSTAT_7    C    "user word"
LSTAT_8    C    "user word"
LSTAT_9    C    "user word"
LSTAT_10   C    "user word"
LSTAT_11   C    "user word"
LSTAT_12   C    "user word"
LSTAT_13   C    "user word"
LSTAT_14   C    "user word"
LSTAT_15   C    "user word"
LSTAT_16   C    "user word"
LSTAT_17   C    "user word"
LSTAT_18   C    "user word"
LSTAT_19   C    "user word"
LSTAT_20   C    "user word"
```

The command STAT is similar to the STAT data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.10   RGET [lrget_1 lrget_2 lrget_3 lrget_4 lrget_5 lrget_6 lrget_7 lrget_8 lrget_9 lrget_10 lrget_11 lrget_12 lrget_13 lrget_14 lrget_15 lrget_16 lrget_17 lrget_18 lrget_19 lrget_20]

```
LRGET_1    C    "user word"
LRGET_2    C    "user word"
LRGET_3    C    "user word"
LRGET_4    C    "user word"
LRGET_5    C    "user word"
LRGET_6    C    "user word"
LRGET_7    C    "user word"
LRGET_8    C    "user word"
LRGET_9    C    "user word"
LRGET_10   C    "user word"
LRGET_11   C    "user word"
LRGET_12   C    "user word"
LRGET_13   C    "user word"
LRGET_14   C    "user word"
LRGET_15   C    "user word"
LRGET_16   C    "user word"
LRGET_17   C    "user word"
LRGET_18   C    "user word"
LRGET_19   C    "user word"
LRGET_20   C    "user word"
```

The command RGET is similar to the RGET data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

13.11 RSAV [lrsave_1 lrsave_2 lrsave_3 lrsave_4 lrsave_5 lrsave_6 lrsave_7 lrsave_8 lrsave_9 lrsave_10 lrsave_11 lrsave_12 lrsave_13 lrsave_14 lrsave_15 lrsave_16 lrsave_17 lrsave_18 lrsave_19 lrsave_20]

```
LRSAVE_1    C   "user word"
LRSAVE_2    C   "user word"
LRSAVE_3    C   "user word"
LRSAVE_4    C   "user word"
LRSAVE_5    C   "user word"
LRSAVE_6    C   "user word"
LRSAVE_7    C   "user word"
LRSAVE_8    C   "user word"
LRSAVE_9    C   "user word"
LRSAVE_10   C   "user word"
LRSAVE_11   C   "user word"
LRSAVE_12   C   "user word"
LRSAVE_13   C   "user word"
LRSAVE_14   C   "user word"
LRSAVE_15   C   "user word"
LRSAVE_16   C   "user word"
LRSAVE_17   C   "user word"
LRSAVE_18   C   "user word"
LRSAVE_19   C   "user word"
LRSAVE_20   C   "user word"
```

The command RSAV is similar to the RSAV data records. It can accept up to 20 4-character words. If the first argument is '.', the number of words is reset to 0 and all the words to four blanks.

Screen views of `GEANT++`

In this section some examples of the `GEANT++` Motif interface are presented.
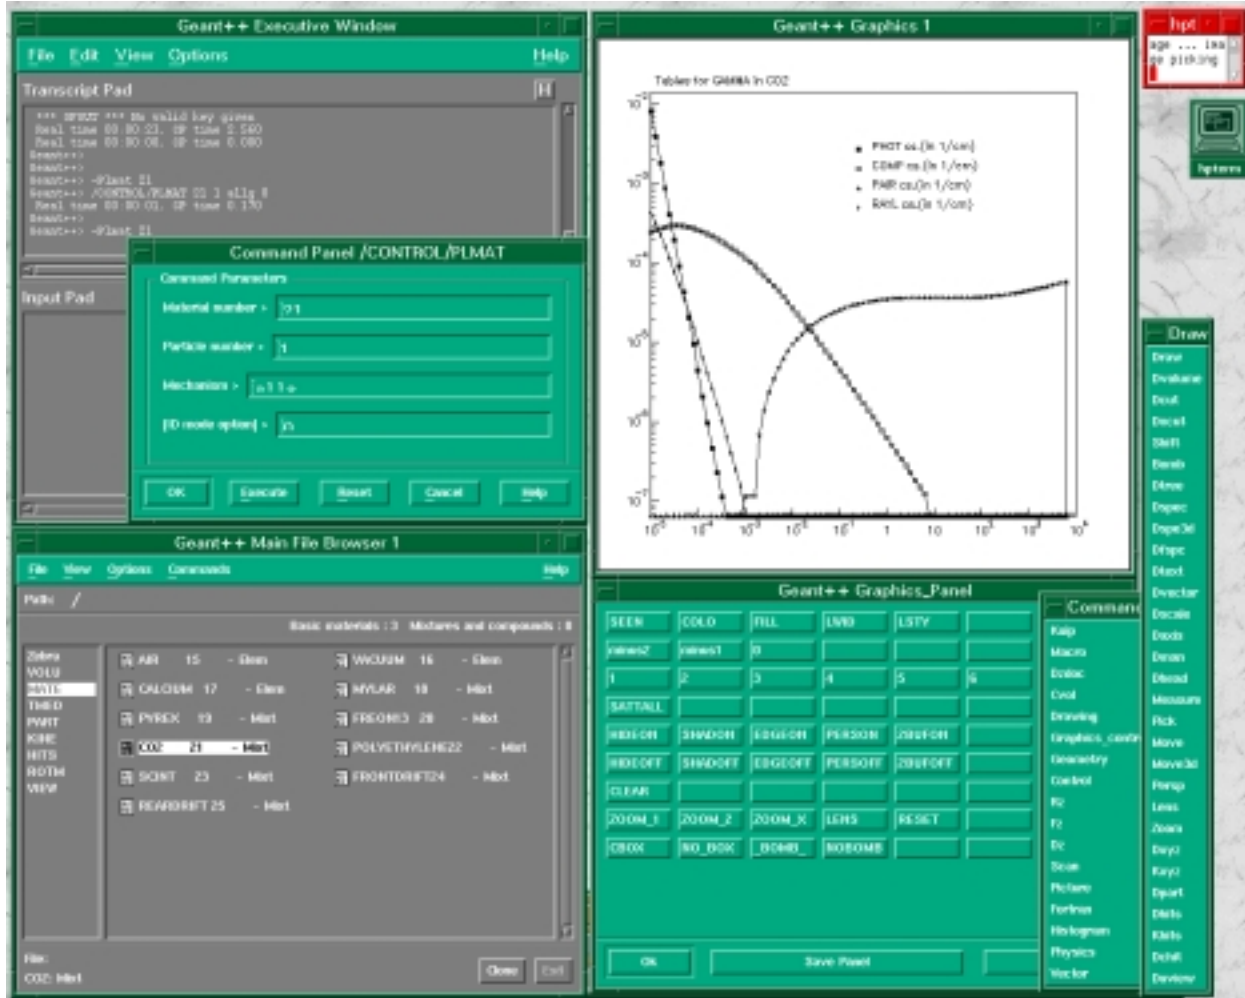

Figure 60: Plotting cross-sections of a material
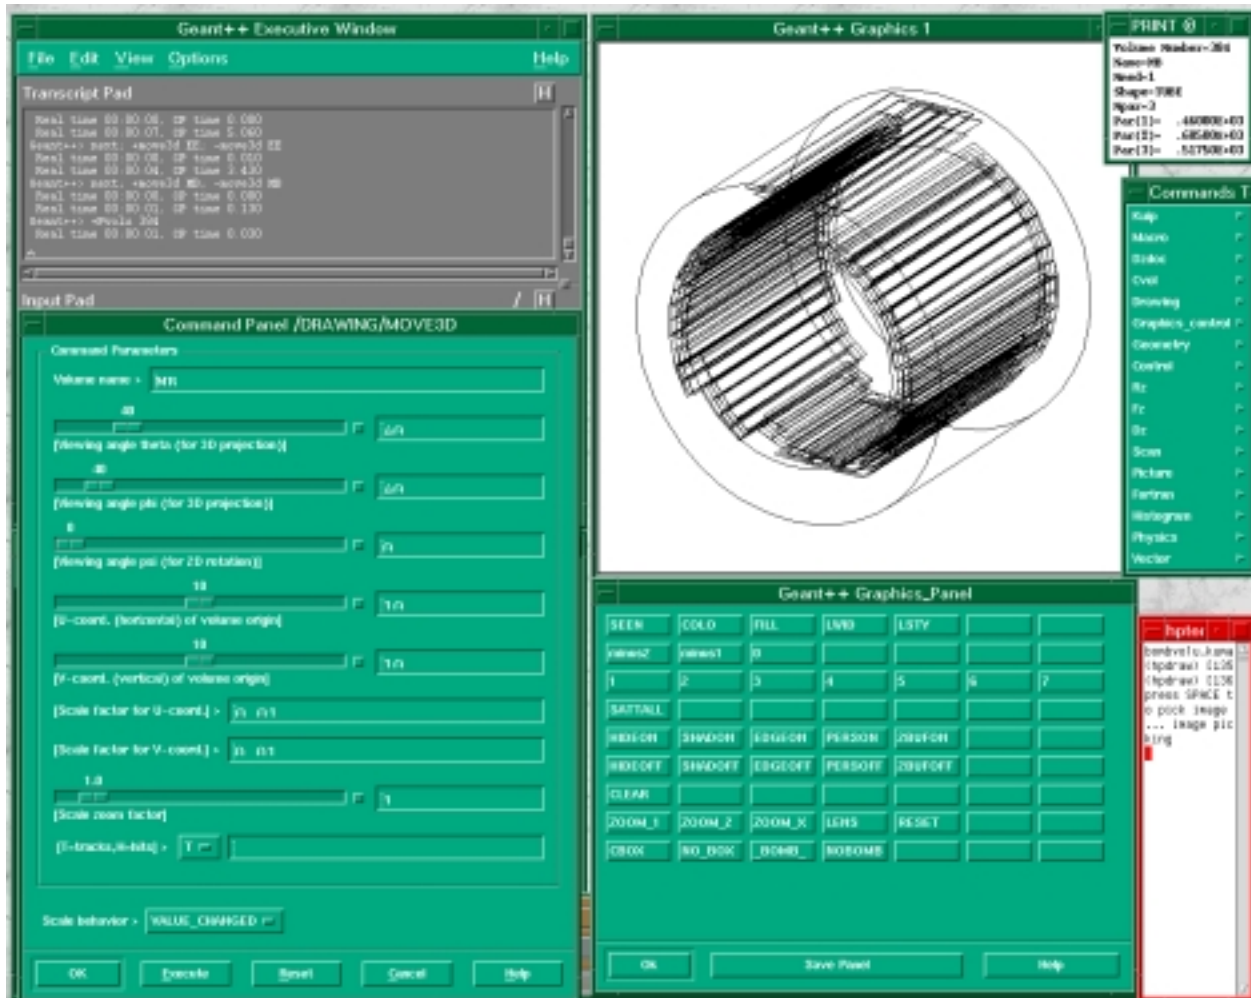

Figure 61: Draw using the MOVE 3D panel
